

## SUPPLEMENTARY MATERIAL

## Model development

## General

5 *Ecosys* is an hourly time-step model with multiple canopy and soil layers that  
6 provide a framework for different plant and microbial populations to acquire, transform  
7 and exchange resources (energy, water, C, N and P). The model is constructed from  
8 algorithms representing basic physical, chemical and biological processes that determine  
9 process rates in plant and microbial populations interacting within complex biomes. These  
10 algorithms interact to simulate complex ecosystem behaviour across a wide range of  
11 spatial and biological scales. The model is designed to represent terrestrial ecosystems  
12 under range of natural and anthropogenic disturbances and environmental changes at patch  
13 (spatially homogenous one-dimensional) and landscape (spatially variable two- or three-  
14 dimensional) scales. A comprehensive description of *ecosys* with a detailed listing of  
15 inputs, outputs, governing equations, parameters, results and references can be found in  
16 Grant (2001). A more detailed description of model algorithms and parameters most  
17 relevant to simulating temperature, water and nutrient effects on net ecosystem  
18 productivity (NEP) is given below, with reference to equations and variable definitions in  
19 appendices A-H below.

## 20 Appendix A: Soil C, N and P transformations

## 21 Decomposition

22 Organic transformations in *ecosys* occur in five organic matter–microbe  
23 complexes (coarse woody litter, fine non-woody litter, animal manure, particulate organic

24 matter (POM), and humus) in each soil layer. Each complex consists of five organic  
25 states: solid organic matter ( $S$ ), dissolved organic matter ( $Q$ ), sorbed organic matter ( $A$ ),  
26 microbial biomass ( $M$ ), and microbial residues ( $Z$ ), among which C, N, and P are  
27 transformed. Organic matter in litter and manure complexes are partitioned from  
28 proximate analysis results into carbohydrate, protein, cellulose, and lignin components of  
29 differing vulnerability to hydrolysis. Organic matter in POM, humus, microbial biomass  
30 and microbial residues in all complexes are also partitioned into components of differing  
31 vulnerability to hydrolysis.

32 The rate at which each component of each organic state in each complex is  
33 hydrolyzed during decomposition is a first-order function of the decomposer biomass ( $M$ )  
34 of all heterotrophic microbial populations [A1]. Decomposer biomasses are redistributed  
35 among complexes from active biomasses according to biomass-substrate concentration  
36 differences (priming) [A3]. The rate at which each component is hydrolyzed is also a  
37 Monod function of substrate concentration [A3, A5], calculated from the fraction of  
38 substrate mass colonized by  $M$  [A4]. Hydrolysis rates are controlled by soil temperature  
39 ( $T_s$ ) through an Arrhenius function [A6] and by soil water content ( $\theta$ ) through its effect  
40 on aqueous microbial concentrations ( $[M]$ ) [A3, A5] in surface litter and in a spatially  
41 resolved soil profile.  $T_s$  and  $\theta$  are calculated from surface energy balances and from heat  
42 and water transfer schemes through canopy–snow–residue–soil profiles. Release of N and  
43 P from hydrolysis of each component in each complex is determined by its N and P  
44 concentrations [A7] which are determined from those of the originating litterfall as  
45 described in *Autotrophic respiration and Growth and senescence* below. Most non-lignin  
46 hydrolysis products are released as dissolved organic C, N and P (DOC, DON, and DOP)

47 which are adsorbed or desorbed according to a power function of their soluble  
48 concentrations [A8-A10].

49 **Microbial growth**

50 The DOC decomposition product is the substrate for heterotrophic respiration ( $R_h$ )  
51 by all  $M$  in each substrate-microbe complex [A13]. Total  $R_h$  for all soil layers [A11]  
52 drives CO<sub>2</sub> emission from the soil surface through volatilization and diffusion.  $R_h$  may be  
53 constrained by microbial N or P concentrations,  $T_s$ , DOC and O<sub>2</sub> [A12 - A14]. O<sub>2</sub> uptake  
54 by  $M$  is driven by  $R_h$  [A16] and constrained by O<sub>2</sub> diffusivity to microbial surfaces [A17],  
55 as described for roots in *Autotrophic respiration and Growth and senescence* below.  
56 Thus  $R_h$  is coupled to O<sub>2</sub> reduction by all aerobic  $M$  according to O<sub>2</sub> availability.  $R_h$  not  
57 coupled with O<sub>2</sub> reduction is coupled with the sequential reduction of NO<sub>3</sub><sup>-</sup>, NO<sub>2</sub><sup>-</sup>, and  
58 N<sub>2</sub>O by heterotrophic denitrifiers, and with the reduction of organic C by fermenters and  
59 acetotrophic methanogens. In addition, autotrophic nitrifiers conduct NH<sub>4</sub><sup>+</sup> and NO<sub>2</sub><sup>-</sup>  
60 oxidation, and NO<sub>2</sub><sup>-</sup> reduction, and autotrophic methanogens and methanotrophs conduct  
61 CH<sub>4</sub> production and oxidation.

62 All microbial populations undergo maintenance respiration ( $R_m$ ) [A18, A19],  
63 depending on microbial N and  $T_s$  as described earlier for plants.  $R_h$  in excess of  $R_m$  is  
64 used in growth respiration  $R_g$  [A20], the energy yield  $\Delta G$  of which drives growth in  
65 biomass  $M$  from DOC uptake according to the energy requirements of biosynthesis [A21-  
66 A22].  $R_m$  in excess of  $R_h$  causes microbial dieback.  $M$  also undergoes first-order  
67 decomposition ( $D_m$ ) [A23]. Internal retention and recycling of microbial N and P during  
68 decomposition [A24] is modelled whenever these nutrients constrain  $R_h$  [A12]. Changes

69 in  $M$  arise from differences between gains from DOC uptake and losses from  $R_m + R_g +$   
70  $D_m$  [A25].

71 **Microbial nutrient exchange**

72 During these changes, all microbial populations seek to maintain set minimum  
73 ratios of C:N or C:P in  $M$  by mineralizing or immobilizing  $\text{NH}_4^+$ ,  $\text{NO}_3^-$  and  $\text{H}_2\text{PO}_4^-$   
74 [A26], thereby controlling solution  $[\text{NH}_4^+]$ ,  $[\text{NO}_3^-]$  and  $[\text{H}_2\text{PO}_4^-]$  that determine root and  
75 mycorrhizal uptake. If immobilization is inadequate to maintain these minimum ratios,  
76 then biomass C:N or C:P may rise, but  $R_h$  is constrained by N or P present in the lowest  
77 concentration with respect to that at the minimum ratio [A12]. Non-symbiotic  
78 heterotrophic diazotrophs can also fix aqueous  $\text{N}_2$  [A27] to the extent that immobilization  
79 is inadequate to maintain their set minimum C:N, but at an additional respiration cost  
80 [A28]. Changes in microbial N and P arise from DON and DOP uptake plus  $\text{NH}_4^+$ ,  $\text{NO}_3^-$   
81 and  $\text{H}_2\text{PO}_4^-$  immobilization and  $\text{N}_2$  fixation, less  $\text{NH}_4^+$ ,  $\text{NO}_3^-$ , and  $\text{H}_2\text{PO}_4^-$  mineralization  
82 and microbial N and P decomposition [A29].

83 **Humification**

84 C, N and P decomposition products in each organic matter-microbe complex are  
85 gradually stabilized into more recalcitrant organic forms with lower C:N and C:P ratios.  
86 Products from lignin hydrolysis [A1, A7] combine with some of the products from  
87 protein and carbohydrate hydrolysis in the litterfall and manure complexes and are  
88 transferred to the POM complex [A31-A34]. Microbial decomposition products [A23-  
89 A24] from all complexes are partitioned between the humus complex and microbial  
90 residues in the originating complex according to soil clay content [A35-A36].

91 **Appendix B: Soil-plant water relations**

92      **Canopy transpiration**

93      Canopy energy exchange in *ecosys* is calculated from an hourly two-stage  
94      convergence solution for the transfer of water and heat through a multi-layered multi-  
95      population soil-root-canopy system. The first stage of this solution requires convergence  
96      to a value of canopy temperature ( $T_c$ ) for each plant population at which the first-order  
97      closure of the canopy energy balance (net radiation ( $R_n$ ), latent heat flux ( $LE$ ) [B1a,b,c],  
98      sensible heat flux ( $H$ ) [B1d], and change in heat storage ( $G$ ) is achieved. These fluxes  
99      are controlled by aerodynamic ( $r_a$ ) [B3] and canopy stomatal ( $r_c$ ) [B2] resistances. Two  
100     controlling mechanisms are postulated for  $r_c$  which are solved in two successive steps:  
101     (1) At the leaf level, leaf resistance ( $r_l$ ) [C4] controls gaseous CO<sub>2</sub> diffusion through each  
102     leaf surface when calculating CO<sub>2</sub> fixation [C1] from concurrent solutions for  
103     diffusion ( $V_g$ ) [C2] and carboxylation ( $V_c$ ) [C3]. The value of  $r_l$  is calculated from a  
104     minimum leaf resistance ( $r_{lmin}$ ) [C5] for each leaf surface that allows a set ratio for  
105     intercellular to canopy CO<sub>2</sub> concentration ( $C_i:C_b$ ) to be maintained at  $V_c$  under  
106     ambient irradiance, air temperature  $T_a$ ,  $C_a$  and zero canopy water potential ( $\psi_c$ ) ( $V_c'$ ).  
107     This ratio will be allowed to vary diurnally as described in *C<sub>3</sub> gross primary*  
108     *productivity* when  $\psi_c$  is solved in the second stage of the convergence solution.  
109     Values of  $r_{lmin}$  are aggregated by leaf surface area to a canopy value ( $r_{cmin}$ ) for use in  
110     the energy balance convergence scheme [B2a].  
111     (2) At the canopy level,  $r_c$  rises from  $r_{cmin}$  at zero  $\psi_c$  from step (1) above through an  
112     exponential function of canopy turgor potential ( $\psi_t$ ) [B2b] calculated from  $\psi_c$  and  
113     osmotic water potential ( $\psi_\pi$ ) [B4] during convergence for transpiration vs. water  
114     uptake.

115 **Root and mycorrhizal water uptake**

116 Root and mycorrhizal water uptake ( $U$ ) [B5] is calculated from the difference  
117 between  $\psi_c$  and soil water potential ( $\psi_s$ ) across soil and root hydraulic resistances ( $\Omega$ <sub>s</sub>  
118 [B9] and  $\Omega_r$  [B10 – B12]) in each rooted soil layer [B6]. Root resistances are calculated  
119 from root radial [B10] and from primary [B11] secondary [B12] axial resistivities using  
120 root lengths and surface areas from a root system submodel [B13] driven by exchange of  
121 nonstructural C, N and P along concentration gradients generated by uptake vs.  
122 consumption of C, N and P in shoots and roots (Grant, 1998a).

123 **Canopy water potential**

124 After convergence for  $T_c$  is achieved, the difference between canopy transpiration  
125 ( $E_c$ ) from the energy balance [B1] and total root water uptake ( $U_c$ ) [B5] from all rooted  
126 layers in the soil is tested against the difference between canopy water content from the  
127 previous hour and that from the current hour [B14]. This difference is minimized in each  
128 iteration by adjusting  $\psi_c$  which in turn determines each of the three terms in [B14].  
129 Because  $r_c$  and  $T_c$  both drive  $E_c$ , the canopy energy balance described in *Canopy*  
130 *transpiration* is recalculated for each adjusted value of  $\psi_c$  during convergence.

131 **Appendix C: Gross primary productivity and autotrophic respiration**

132  **$C_3$  gross primary productivity**

133 After successful convergence for  $T_c$  and  $\psi_c$  as described in *Canopy transpiration*,  
134  $V_c$  is recalculated from that under zero  $\psi_c$  ( $V_c'$ ) to that under ambient  $\psi_c$ . This  
135 recalculation is driven by stomatal effects on  $V_g$  [C2] from the increase in  $r_{lmin}$  at zero  $\psi_c$   
136 [C5] to  $r_c$  at ambient  $\psi_c$  [C4], and by non-stomatal effects( $f_\psi$ ) [C9] on CO<sub>2</sub>- and light-  
137 limited carboxylation ( $V_b$ ) [C6] and  $V_j$  [C7] (Grant and Flanagan, 2007). The

138 recalculation of  $V_c$  is accomplished through a convergence solution for  $C_i$  and its aqueous  
139 counterpart  $C_c$  at which  $V_g$  [C2] equals  $V_c$  [C3] (Grant and Flanagan, 2007). The  $\text{CO}_2$   
140 fixation rate of each leaf surface at convergence is added to arrive at a value for gross  
141 primary productivity (GPP) by each plant population in the model [C1]. The  $\text{CO}_2$  fixation  
142 product is stored in nonstructural C pools ( $\sigma_C$ ) in each branch.

143 GPP is strongly controlled by nutrient uptake ( $U_{\text{NH}_4}$ ,  $U_{\text{NO}_3}$  and  $U_{\text{PO}_4}$  [C23]),  
144 products of which are added to nonstructural N ( $\sigma_N$ ) and P ( $\sigma_P$ ) in root and mycorrhizal  
145 layers where they are coupled with  $\sigma_C$  to drive growth of branches, roots and  
146 mycorrhizae as described in *Growth and senescence*. Low  $\sigma_N:\sigma_C$  or  $\sigma_P:\sigma_C$  in branches  
147 indicate excess  $\text{CO}_2$  fixation with respect to N or P uptake for phytomass growth. Such  
148 ratios in the model have two effects on GPP:

149 (1) They reduce activities of rubisco [C6a] and chlorophyll [C7a] through product  
150 inhibition [C11], thereby simulating the suppression of  $\text{CO}_2$  fixation by leaf  $\sigma_C$   
151 accumulation widely reported in the literature.

152 (2) They reduce the structural N:C and P:C ratios at which leaves are formed because  $\sigma_C$ ,  
153  $\sigma_N$  and  $\sigma_P$  are the substrates for leaf growth. Lower structural ratios cause a  
154 proportional reduction in areal concentrations of rubisco [C6b] and chlorophyll [C7b],  
155 reducing leaf  $\text{CO}_2$  fixation.

## 156 **Autotrophic respiration**

157 The temperature dependent oxidation of these nonstructural pools ( $R_c$ ) [C14], plus  
158 the energy costs of nutrient uptake [C23], drive autotrophic respiration ( $R_a$ ) [C13] by all  
159 branches, roots and mycorrhizae.  $R_c$  by roots and mycorrhizae is constrained by  $\text{O}_2$   
160 uptake ( $U_{\text{O}_2}$ ) [C14b] calculated by solving for aqueous  $\text{O}_2$  concentrations at root and

161 mycorrhizal surfaces ( $[O_{2r}]$ ) at which convection + radial diffusion through the soil  
162 aqueous phase plus radial diffusion through the root aqueous phase [C14d] equals active  
163 uptake driven by  $O_2$  demand from  $R_c$  [C14c] (Grant, 2004). These diffusive fluxes are in  
164 turn coupled to volatilization -dissolution between aqueous and gaseous phases in soil  
165 and root [D14]. The diffusion processes are driven by aqueous  $O_2$  concentrations  
166 sustained by transport and dissolution of gaseous  $O_2$  through soil and roots (Grant, 2004),  
167 and are governed by lengths and surface areas of roots and mycorrhizae (Grant, 1998a).  
168 Thus  $R_c$  is coupled to  $O_2$  reduction by all root and mycorrhizal populations according to  
169  $O_2$  availability.  $R_c$  is first used to meet maintenance respiration requirements ( $R_m$ ),  
170 calculated independently of  $R_c$  from the N content in each organ, and a function of  $T_c$  or  
171  $T_s$  [C16]. Any excess of  $R_c$  over  $R_m$  is expended as growth respiration ( $R_g$ ), constrained  
172 by branch, root or mycorrhizal  $\psi_t$  [C17]. When  $R_m$  exceeds  $R_c$ , the shortfall is met by the  
173 respiration of remobilizable C ( $R_s$ ) in leaves and twigs or roots and mycorrhizae [C15].

174 **Growth and senescence**

175  $R_g$  drives the conversion of branch  $\sigma_C$  into foliage, twigs, branches, boles and  
176 reproductive material according to organ growth yields ( $Y_g$ ) and phenology-dependent  
177 partitioning coefficients [C20], and the conversion of root and mycorrhizal  $\sigma_C$  into  
178 primary and secondary axes according to root and mycorrhizal growth yields. Growth  
179 also requires organ-specific ratios of nonstructural N ( $\sigma_N$ ) and P ( $\sigma_P$ ) from  $U_{NH_4}$ ,  $U_{NO_3}$   
180 and  $U_{PO_4}$  [C23] which are coupled with  $\sigma_C$  to drive growth of branches, roots and  
181 mycorrhizae.

182 The translocation of  $\sigma_C$ ,  $\sigma_N$  and  $\sigma_P$  among branches and root and mycorrhizal  
183 layers is driven by concentration gradients generated by production of  $\sigma_C$  from branch

184 GPP and of  $\sigma_N$  and  $\sigma_P$  from root and mycorrhizal uptake vs. consumption of  $\sigma_C$ ,  $\sigma_N$  and  
185  $\sigma_P$  from  $R_c$ ,  $R_g$  and phytomass growth (Grant, 1998a). Low  $\sigma_N:\sigma_C$  or  $\sigma_P:\sigma_C$  in  
186 mycorrhizae and roots indicates inadequate N or P uptake with respect to  $\text{CO}_2$  fixation.  
187 These ratios affect translocation of  $\sigma_C$ ,  $\sigma_N$  and  $\sigma_P$  by lowering mycorrhizal-root-branch  
188 concentration gradients of  $\sigma_N$  and  $\sigma_P$  while raising branch-root-mycorrhizal concentration  
189 gradients of  $\sigma_C$ . These changes slow transfer of  $\sigma_N$  and  $\sigma_P$  from root to branch and hasten  
190 transfer of  $\sigma_C$  from branch to root, increasing root and mycorrhizal growth at the expense  
191 of branch growth, and thereby raising N and P uptake [C23] with respect to  $\text{CO}_2$  fixation.  
192 Conversely, high  $\sigma_N:\sigma_C$  or  $\sigma_P:\sigma_C$  in roots and mycorrhizae indicate excess N or P uptake  
193 with respect to  $\text{CO}_2$  fixation. Such ratios reduce specific activities of root and  
194 mycorrhizal surfaces for N or P uptake through a product inhibition function as has been  
195 observed experimentally. These changes hasten transfer of  $\sigma_N$  and  $\sigma_P$  from root to branch  
196 and slow transfer of  $\sigma_C$  from branch to root, increasing branch growth at the expense of  
197 root and mycorrhizal growth, and thereby slowing N and P uptake. Thus the modelled  
198 plant translocates  $\sigma_C$ ,  $\sigma_N$  and  $\sigma_P$  among branches, roots and mycorrhizae to maintain a  
199 functional equilibrium between acquisition and use of C, N and P by different parts of the  
200 plant.

201  $R_g$  is limited by  $\psi_t$  [C17], and because branch  $\psi_t$  declines relatively more with soil  
202 drying than does root  $\psi_t$ , branch  $R_g$  also declines relatively more with soil drying than  
203 does root  $R_g$ , slowing oxidation of  $\sigma_C$  in branches and allowing more translocation of  $\sigma_C$   
204 from branches to roots. This change in allocation of  $\sigma_C$  enables more root growth to  
205 reduce  $\Omega_s$ ,  $\Omega_r$  and  $\Omega_a$ , and hence increase  $U$  [B6], thereby offsetting the effects of soil

206 drying on  $\psi$ . Thus the modelled plant translocates  $\sigma_C$ ,  $\sigma_N$  and  $\sigma_P$  among branches, roots  
207 and mycorrhizae to maintain a functional equilibrium between acquisition and use of  
208 water.

209  $R_s$  [C15] drives the withdrawal of remobilizable C, N and P (mostly nonstructural  
210 protein) from leaves and twigs or roots and mycorrhizae into  $\sigma_N$  and  $\sigma_P$ , and the loss of  
211 associated non-remobilizable C, N and P (mostly structural) as litterfall [C18]. Provision  
212 is also made to withdraw remobilizable N or P from leaves and twigs or roots and  
213 mycorrhizae when ratios of  $\sigma_N:\sigma_C$  or  $\sigma_P:\sigma_C$  become smaller than those required for  
214 growth of new phytomass. This withdrawal drives the withdrawal of associated  
215 remobilizable C, and the loss of associated non-remobilizable C, N and P as litterfall.  
216 Environmental constraints such as water, heat, nutrient or  $O_2$  stress that reduce  $\sigma_C$  and  
217 hence  $R_c$  with respect to  $R_m$  therefore hasten litterfall.

218  $R_a$  of each branch or root and mycorrhizal layer is the total of  $R_c$  and  $R_s$ , and net  
219 primary productivity (NPP) is the difference between canopy GPP [C1] and total  $R_a$  of all  
220 branches and root and mycorrhizal layers [C13]. Phytomass net growth is the difference  
221 between gains driven by  $R_g$  and  $Y_g$ , and losses driven by  $R_s$  and litterfall [C20]. These  
222 gains are allocated to leaves, twigs, wood and reproductive material at successive branch  
223 nodes, and to roots and mycorrhizae at successive primary and secondary axes, driving  
224 leaf expansion [C21a] and root extension [C21b]. Losses from remobilization and  
225 litterfall in shoots start at the lowest node of each branch at which leaves or twigs are  
226 present, and proceed upwards when leaves or twigs are lost. Losses in roots and  
227 mycorrhizae start with secondary axes and proceeds to primary axes when secondary  
228 axes are lost.

229 **Root and mycorrhizal nutrient uptake**

230 Root and mycorrhizal uptake of N and P ( $U_{\text{NH}_4}$ ,  $U_{\text{NO}_3}$  and  $U_{\text{PO}_4}$ ) is calculated by  
231 solving for solution  $[\text{NH}_4^+]$ ,  $[\text{NO}_3^-]$  and  $[\text{H}_2\text{PO}_4^-]$  at root and mycorrhizal surfaces at  
232 which radial transport by mass flow and diffusion from the soil solution to these surfaces  
233 [C23a,c,e] equals active uptake by the surfaces [C23b,d,f]. Path lengths and surface areas  
234 for  $U_{\text{NH}_4}$ ,  $U_{\text{NO}_3}$  and  $U_{\text{PO}_4}$  are calculated from a root and mycorrhizal growth submodel  
235 driven by exchange of nonstructural C, N and P along concentration gradients generated  
236 by uptake vs. consumption of C, N and P in shoots and roots (Grant, 1998a). A product  
237 inhibition function is included to avoid uptake in excess of nutrient requirements [C23g].

238 **C<sub>4</sub> gross primary productivity**

239 **C<sub>4</sub> mesophyll**

240 In C<sub>4</sub> plants, the mesophyll carboxylation rate is the lesser of CO<sub>2</sub>- and light-  
241 limited reaction rates [C26] (Berry and Farquhar, 1978). The CO<sub>2</sub>-limited rate is a  
242 Michaelis-Menten function of PEP carboxylase (PEPc) activity and aqueous CO<sub>2</sub>  
243 concentration in the mesophyll [C29] parameterized from Berry and Farquhar (1978) and  
244 from Edwards and Walker (1983). The light-limited rate [C30] is a hyperbolic function of  
245 absorbed irradiance and mesophyll chlorophyll activity [C31] with a quantum  
246 requirement based on 2 ATP from Berry and Farquhar (1978). PEPc [C32] and  
247 chlorophyll [C33] activities are calculated from specific activities multiplied by set  
248 fractions of leaf surface N density, and from functions of C<sub>4</sub> product inhibition (Jiao and  
249 Chollet, 1988; Lawlor, 1993) [C34],  $\psi_c$  [C35] as described in Grant and Flanagan  
250 (2007)) and  $T_c$  [C36]. Leaf surface N density is controlled by leaf structural N:C and P:C

251 ratios calculated during leaf growth from leaf non-structural N:C and P:C ratios arising  
252 from root N and P uptake (Grant, 1998a) vs. CO<sub>2</sub> fixation.

253 **C<sub>4</sub> mesophyll-bundle sheath exchange**

254 Differences in the mesophyll and bundle sheath concentrations of the C<sub>4</sub>  
255 carboxylation product drive mesophyll-bundle sheath transfer (Leegood, 2000) [C37].  
256 The bundle sheath concentration of the C<sub>4</sub> product drives a product-inhibited  
257 decarboxylation reaction (Laisk and Edwards, 2000) [C38], the CO<sub>2</sub> product of which  
258 generates a concentration gradient that drives leakage of CO<sub>2</sub> from the bundle sheath to  
259 the mesophyll [C39]. CO<sub>2</sub> in the bundle sheath is maintained in 1:50 equilibrium with  
260 HCO<sub>3</sub><sup>-</sup> (Laisk and Edwards, 2000). At this stage of model development, the return of a C<sub>3</sub>  
261 decarboxylation product from the bundle sheath to the mesophyll is not simulated.  
262 Parameters used in Eqs. [C37-C39] allowed mesophyll and bundle sheath concentrations  
263 of C<sub>4</sub> carboxylation products from [C40-C41] to be maintained at values consistent with  
264 those in Leegood (2000), bundle sheath concentrations of CO<sub>2</sub> (from [C42]) to be  
265 maintained at values similar to those reported by Furbank and Hatch (1987), and bundle  
266 sheath CO<sub>2</sub> leakiness [C39]), expressed as a fraction of PEP carboxylation, to be  
267 maintained at values similar to those in Williams et al. (2001), in sorghum as described in  
268 Grant et al. (2004).

269 **C<sub>4</sub> bundle sheath**

270 A C<sub>3</sub> model in which carboxylation is the lesser of CO<sub>2</sub>- and light-limited reaction  
271 rates (Farquhar et al., 1980) has been parameterized for the bundle sheath of C<sub>4</sub> plants  
272 [C43] from Seeman et al. (1984). The CO<sub>2</sub>-limited rate [C44] is a Michaelis-Menten  
273 function of RuBP carboxylase (RuBPc) activity and bundle sheath CO<sub>2</sub> concentration

274 [C42]. The light-limited rate [C45] is a hyperbolic function of absorbed irradiance and  
275 activity of chlorophyll associated with the bundle sheath with a quantum yield based on 3  
276 ATP [C46]. The provision of reductant from the mesophyll to the bundle sheath in  
277 NADP-ME species is not explicitly simulated. RuBPc [C47] and chlorophyll [C48]  
278 activities are the products of specific activities and concentrations multiplied by set  
279 fractions of leaf surface N density, and from functions of C<sub>3</sub> product inhibition (Bowes,  
280 1991; Stitt, 1991) [C49],  $\psi_c$  ([A12] from Grant and Flanagan (2007)) and  $T_c$  [C36].

281 Rates of C<sub>3</sub> product removal are controlled by phytomass biosynthesis rates  
282 driven by concentrations of nonstructural products from leaf CO<sub>2</sub> fixation and from root  
283 N and P uptake. If biosynthesis rates are limited by nutrient uptake, consequent depletion  
284 of nonstructural N or P and accumulation of nonstructural C will constrain specific  
285 activities of RuBP and chlorophyll [C47-C49], and thereby slow C<sub>3</sub> carboxylation [C43],  
286 raise bundle sheath CO<sub>2</sub> concentration [C42], accelerate CO<sub>2</sub> leakage [C39], slow C<sub>4</sub>  
287 decarboxylation [C38], raise C<sub>4</sub> product concentration in the bundle sheath [C41], slow  
288 C<sub>4</sub> product transfer from the mesophyll [C37], raise C<sub>4</sub> product concentration in the  
289 mesophyll [C40], and slow mesophyll CO<sub>2</sub> fixation [C32-C35]. This reaction sequence  
290 simulates the progressive inhibition of C<sub>3</sub> and C<sub>4</sub> carboxylation hypothesized by Sawada  
291 et al. (2002) following partial removal of C sinks in C<sub>4</sub> plants.

292 **Appendix D: Soil water, heat, gas and solute fluxes**

293 **Surface water flux**

294 Surface runoff is modelled using Manning's equation [D1] with surface water  
295 velocity ( $v$ ) [D3] calculated from surface geometry [D5a] and slope [D5b], and with

296 surface water depth ( $d$ ) [D2] calculated from surface water balance [D4] using kinematic  
297 wave theory.

298 **Subsurface water flux**

299 Subsurface water flow [D7] is calculated from Richard's equation using bulk soil  
300 water potentials ( $\psi_s$ ) of both cells if both source and destination cells are unsaturated  
301 [D9a], or Green-Ampt equation using  $\psi_s$  beyond the wetting front of the unsaturated cell  
302 if either source or destination cell is saturated [D9b] (Grant et al., 2004). Subsurface  
303 water flow can also occur through macropores using Poiseulle-Hagen theory for laminar  
304 flow in tubes (Dimitrov et al., 2010), depending on inputs for macropore volume fraction.

305 **Exchange with water table**

306 If a water table is present in the model, subsurface boundary water fluxes between  
307 saturated boundary grid cells and a fixed external water table are calculated from lateral  
308 hydraulic conductivities of the grid cells, and from elevation differences and lateral  
309 distances between the grid cells and the external water table [D10]. These terms are  
310 determined from set values for the external water table depth ( $WTD_x$ ) of, and lateral  
311 distance ( $L_t$ ) to, an external water table.

312 **Surface heat flux**

313 Surface heat fluxes ( $G$ ) arising from closure of the energy balance at snowpack,  
314 surface litter and soil surfaces [D11] (Grant et al., 1999) drive conductive-convective  
315 fluxes among snowpack, surface litter and soil layers [D12]. These fluxes drive freezing-  
316 thawing ( $Q_f$ ) and changes temperatures ( $T$ ) in snowpack, surface litter and soil layers  
317 [D13].

318 **Gas flux**

319 All gases undergo volatilization-dissolution between the gaseous and aqueous  
320 phases in the soil [D14a] and root [D14b], and between the atmosphere and the aqueous  
321 phase at the soil surface [D15a], driven by gaseous-aqueous concentration differences  
322 calculated from solubility coefficients and coupled to diffusive uptake by roots [C14] and  
323 microbes [A17]. Gases also undergo convective-conductive transfer among soil layers  
324 driven by gaseous concentration gradients and diffusivities [D16a,b,c] calculated from  
325 air-filled porosities [D17a,b,c], and from each rooted soil layer directly to the atmosphere  
326 through roots driven by gaseous concentration gradients and diffusivities [D16d]  
327 calculated from root porosities [D17d]. Gases may also bubble upwards from soil zones  
328 in which the total partial pressure of all aqueous gases exceeds atmospheric pressure  
329 [D18].

330 **Solute flux**

331 All gaseous and non-gaseous solutes undergo convective-dispersive transfer  
332 among soil layers driven by aqueous concentration gradients and dispersivities [D19]  
333 calculated from water-filled porosity [D20] and water flow length [D21].

334 **Appendix E: Solute transformations**

335 **Precipitation-dissolution equilibria**

336 Solution  $[\text{NH}_4^+]$ ,  $[\text{NO}_3^-]$  and  $[\text{H}_2\text{PO}_4^-]$  that drive  $U_{\text{NH}_4}$ ,  $U_{\text{NO}_3}$  and  $U_{\text{PO}_4}$  [C23] are  
337 controlled by precipitation, adsorption and ion pairing reactions (Grant and Heaney,  
338 1997; Grant et al., 2004), including precipitation-dissolution of  $\text{Al}(\text{OH})_3$ ,  $\text{Fe}(\text{OH})_3$ ,  
339  $\text{CaCO}_3$ ,  $\text{CaSO}_4$ ,  $\text{AlPO}_4$ ,  $\text{FePO}_4$ ,  $\text{Ca}(\text{H}_2\text{PO}_4)_2$ ,  $\text{CaHPO}_4$ , and  $\text{Ca}_5(\text{PO}_4)_3\text{OH}$  [E1 – E9],  
340 cation exchange between  $\text{Ca}^{2+}$ ,  $\text{NH}_4^+$  and other cations [E10 – E15], anion exchange

341 between adsorbed and soluble  $\text{H}_2\text{PO}_4^-$ ,  $\text{HPO}_4^{2-}$  and  $\text{OH}^-$  [E16 – E20], and ion pairing  
342 [E22 – E55].

#### 346 **Appendix F: N<sub>2</sub> fixation**

##### 347 **Rhizobial growth**

348 Modelling the activity of symbiotic N<sub>2</sub> fixing bacteria in roots follows a protocol  
349 similar to that of non-symbiotic N<sub>2</sub> fixing bacteria in soil. Respiration demand is driven  
350 by specific activity, microbial biomass ( $M_n$ ), and nonstructural C concentration ( $[\chi_n]$ ) in  
351 root nodules [F1], and is constrained by temperature [F2] and microbial N or P status  
352 [F3]. Nodule respiration ( $R$ ) is constrained by the extent to which O<sub>2</sub> uptake meets O<sub>2</sub>  
353 demand [F4] imposed by respiration demand [F5]. O<sub>2</sub> uptake is in turn constrained by  
354 rhizosphere [O<sub>2r</sub>] [F6a] which is controlled by radial diffusion of O<sub>2</sub> through soil water to  
355 roots and nodules [F6b]. Soil water [O<sub>2</sub>] is maintained by dissolution of O<sub>2</sub> from soil air  
356 which is in turn maintained by soil-atmosphere gas exchange and vertical diffusion  
357 (Grant, 2004).  $R_h$  is first allocated to maintenance respiration  $R_m$  [F7-F8] and the  
358 remainder if any is allocated to growth respiration  $R_g$  [F9]. If  $R_m$  exceeds  $R_h$ , the shortfall  
359 is made up from respiration of microbial protein C, forcing senescence and litterfall of  
360 associated non-protein C [F10-F11].

##### 361 **N<sub>2</sub> fixation**

362 N<sub>2</sub> fixation  $V_{N_2}$  is driven by  $R_g$  [F12], but is constrained by accumulation of  
363 nonstructural N ( $\nu_n$ ) with respect to nonstructural C and P also required for microbial

364 growth in the nodule [F13].  $v_n$  is the product of  $V_{N_2}$ , so that [F12] simulates the inhibition  
365 of  $N_2$  fixation by its product (Postgate, 1998). The value of  $V_{N_2}$  is also limited by the  
366 additional N needed to maintain bacterial N content [ $N_n'$ ] of  $M_n$  [F12], so that  $N_2$  fixation  
367 is constrained by the need of nodule bacteria for N not met from other sources (Postgate,  
368 1998). Respiration required for  $N_2$  fixation  $R_{N_2}$  [F14] is subtracted from  $R_g$  [F15] when  
369 calculating microbial growth [F16-F18]. Microbial senescence drives N and P litterfall  
370 [F19-F20].

371 **Nodule-root exchange**

372 Exchange of nonstructural C, N and P between roots and nodules is driven by  
373 concentration gradients [F21-F23] created by generation, transfer and consumption of  
374 nonstructural C, N and P in shoots, roots, mycorrhizae and nodules. Nonstructural C is  
375 generated in shoots and transferred along concentration gradients to roots and thence to  
376 nodules [F21]. Nonstructural P is generated in roots and transferred along concentration  
377 gradients to shoots and nodules [F23]. Nonstructural N is generated in roots through  
378 mineral uptake and in nodules through gaseous fixation [F22]. Nonstructural C, N and P  
379 in nodules is determined by root-nodule exchange, by nodule respiration and fixation, and  
380 by remobilization from nodule litterfall [F24-F26].

381 Root nonstructural N ( $v_r$ ) may rise if high mineral N concentrations in soil sustain  
382 rapid N uptake by roots. Large  $v_r$  suppresses or even reverses the transfer of  $v_n$  from  
383 nodule to root [F22], raising  $v_n$  [F25] and hence suppressing  $V_{N_2}$  [F12-F13]. Large  $v_r$   
384 also accelerates the consumption of  $\chi_r$ , slowing its transfer to nodules [F21], reducing  
385  $\chi_n$  [F24] and hence slowing nodule growth [F1]. Conversely, slow root N uptake

386 caused by low soil mineral N concentrations would lower  $\nu_{rt}$  and raise  $\chi_{rt}$ , hastening the  
387 transfer of  $\nu_n$  from nodule to root and of  $\chi_{rt}$  from root to nodule, lowering  $\nu_n$ , raising  $\chi_n$ ,  
388 and accelerating  $V_{N_2}$ . However [F13] also allows  $V_{N_2}$  to be constrained by nonstructural C  
389 and P concentrations arising from  $CO_2$  fixation and root P uptake.

390 **Appendix G:  $CH_4$  production and consumption**

391 **Anaerobic fermenters and  $H_2$  producing acetogens**

392 The states  $S_{i,j,k}$ ,  $B_{i,k}$  and  $Z_{i,j,k}$  in *ecosys* are substrates for hydrolysis by all active ( $j$   
393 =  $a$ ) heterotrophic biomass communities ( $M_{i,n,a}$ ) [G1-G7] (Grant et al., 1993a), which  
394 include fermenters plus acetogens. Hydrolysis products are transferred to soluble organic  
395 matter ( $DOC_{i,k}$ ) which is the substrate for respiration and uptake by microbial biomass  
396 ( $M_{i,n,j}$ ) as described for aerobic heterotrophs [G11] (Grant et al., 1993a). Respiration ( $R_{i,f}$ )  
397 of  $DOC_{i,c}$  by fermenters plus acetogens ( $n = f$ ) is a Michaelis-Menten function of  $[DOC_{i,c}]$   
398 inhibited by  $O_2$  [G1]. Respiration products are partitioned among  $A_{i,c}$ ,  $CO_2$  and  $H_2$  according  
399 to Brock and Madigan (1991) [G2].  $R_{i,f}$  beyond that used for maintenance respiration drives  
400 the uptake of additional  $DOC_{i,c}$  [G3] for microbial growth according to the growth yield ( $Y_f$ )  
401 from fermentation [G4]. The growth yield from fermentation is calculated by dividing the  
402 free energy change of fermentation, adjusted for  $H_2$  product concentration [G5], by the  
403 energy required to transform soluble organic C into microbial C [G4]. Change in  $M_{i,f,j}$  is  
404 thus the difference between uptake and respiration of  $DOC_{i,c}$ , less decomposition [G6]. This  
405 change determines  $M_{i,f,a}$  used in the following calculation of  $R_{i,f}$  [G1]. Ratios of  $M_{i,f,j,c}$  to  
406  $M_{i,f,j,n}$  determine mineralization-immobilization of N [G23] (Grant et al., 1993a).  
407 Decomposition products ( $D_{i,f,j,k}$ ) are partitioned to microbial residues ( $Z_{i,j,k}$ ) and soil

408 organic matter ( $S_{i,j,k}$ ) (where  $i$  = passive soil organic matter) [G26-G28] (Grant et al., 1993a)  
409 which undergo further hydrolysis.

410 **Acetotrophic methanogens**

411 The fermenter product ( $A_{i,c}$ ) [G2] is the substrate for respiration ( $R_{i,m}$ ) by  
412 acetotrophic methanogens ( $n = m$ ) [G7]. Respiration products are partitioned between  $CH_4$   
413 and  $CO_2$  according to Brock and Madigan (1991) [G8].  $R_{i,m}$  beyond that used for  
414 maintenance respiration drives the uptake of additional  $A_{i,c}$  [G9] for microbial growth  
415 according to the growth yield ( $Y_m$ ) of acetotrophic methanogenesis [G10]. This growth yield  
416 is calculated by dividing the free energy change of acetotrophic methanogenesis (Brock and  
417 Madigan, 1991) by the energy required to transform acetate into microbial C. Acetogenic  
418 methanogens in the model use acetate as their sole carbon and energy source (Smith and  
419 Mah, 1980). Change in  $M_{i,m,j}$  is thus the difference between uptake and respiration of  $A_{i,c}$ ,  
420 less decomposition [G11]. This change determines  $M_{i,m,a}$  used in the following calculation  
421 of  $R_{i,m}$  [G7]. Mineralization and decomposition processes are the same as those for other  
422 microbial populations.

423 **Hydrogenotrophic methanogens**

424 The fermenter products  $CO_2$  and  $H_2$  [G2] are the substrates for  $CO_2$  reduction by  
425 hydrogenotrophic methanogens ( $n = h$ ) which are assumed to be autotrophic [G12].  
426 Respiration products are partitioned between  $CH_4$  and  $H_2O$  according to Brock and Madigan  
427 (1991) [G13].  $R_h$  beyond that used for maintenance respiration drives the uptake of  
428 additional  $CO_2$  [G14] for microbial growth according to the growth yield ( $Y_h$ ) of  
429 hydrogenotrophic methanogenesis (Brock and Madigan, 1991) [G15]. This growth yield is  
430 calculated by dividing the free energy change of hydrogenotrophic methanogenesis, adjusted

431 for  $H_2$  substrate concentration [G16], by the energy required to transform  $CO_2$  into microbial  
432 C. Change in  $M_{h,j}$  is thus the difference between uptake and respiration of  $CO_2$ , less  
433 decomposition [G17]. This change determines  $M_{h,a}$  used in the following calculation of  $R_h$   
434 [G12]. Mineralization and decomposition processes are the same as those for other microbial  
435 populations.

436 **Autotrophic methanotrophs**

437 Methane generated by acetotrophic and hydrogenotrophic methanogens is the  
438 substrate for  $CH_4$  oxidation by autotrophic methanotrophs ( $n = t$ ) [G18]. The stoichiometry  
439 and energetics of the methanotrophic reactions [G22-G24] are based on those of  $CH_4$  to  $CO_2$   
440 in Brock and Madigan (1991). The oxidation of  $CH_4$  to  $CO_2$  is coupled through an energy  
441 yield with the oxidation of  $CH_4$  to organic C used in microbial respiration [G19]. The energy  
442 yield from  $CH_4$  oxidation is calculated by dividing the free energy change of  $CH_4$  oxidation  
443 by the energy required to transform  $CH_4$  into organic C [G20]. Oxygen requirements to  
444 sustain  $CH_4$  oxidation rates are then calculated from the stoichiometries of  $CH_4$  oxidation  
445 [G22-G23] and aerobic microbial respiration [G24]. The  $O_2$  concentrations at  
446 methanotrophic microsites are then found at which active  $O_2$  uptake driven by requirements  
447 for  $CH_4$  oxidation equals spherical  $O_2$  diffusion to the microsites from the soil solution.  
448 These microsites are considered to be uniformly distributed on soil surfaces and are separated  
449 from the soil atmosphere (if present) by a water film of uniform thickness that depends upon  
450 soil water potential. The  $O_2$  uptake by each aerobic microbial population in the model  
451 competes with that by all other aerobic microbial populations (e.g. Grant and Rochette, 1994;  
452 Grant, 1995], and is constrained by  $O_2$  transfer rates through the gaseous and aqueous phases  
453 of the soil profile. The ratio of  $O_2$  uptake to  $O_2$  requirement ( $f_{O_2t}$ ) is then used to constrain

454 CH<sub>4</sub> oxidation rates [G21] so that CH<sub>4</sub> oxidation is stoichiometrically coupled to O<sub>2</sub> uptake.  
455 Growth respiration by methanotrophs is calculated as the difference between total respiration  
456 (R<sub>t</sub>) from eq. [G21b] and maintenance respiration (R<sub>mt</sub>) from eqs. [G18-G19] (Grant et al.,  
457 1993a). Growth respiration drives the uptake and transformation of additional CH<sub>4</sub> into  
458 microbial biomass (M<sub>t,c</sub>) [G25]) according to the growth yield. This yield is calculated by  
459 dividing the free energy change of CH<sub>4</sub> oxidation (Brock and Madigan, 1991) [G18] by the  
460 energy required to construct new microbial biomass from CH<sub>4</sub> [G26]. Net growth of the  
461 methanotrophic population M<sub>t,j,c</sub> is calculated as the uptake of CH<sub>4</sub>-C minus respiration and  
462 decomposition of assimilated C [G27]. This change determines M<sub>t,a</sub> used in the following  
463 calculation of X' <sub>t</sub> [G18]). Mineralization and decomposition processes are the same as those  
464 for other microbial populations.

465 This submodel of autotrophic methanotrophy has been used to simulate  
466 methanotrophic growth yields, specific growth rates, CH<sub>4</sub> concentration profiles and the  
467 sensitivity of CH<sub>4</sub> uptake to temperature and water content in soil columns (Grant, 1999).  
468 The combined submodels of anaerobic fermentation, acetotrophic methanogenesis,  
469 hydrogenotrophic methanogenesis and autotrophic methanotrophy have been used to  
470 simulate methanogenic growth yields, specific growth rates, and the time course of CH<sub>4</sub>  
471 emissions from differently amended soil columns at different temperatures (Grant, 1998b).  
472 All input parameter values used in eqs. [G1-G27] were derived from the microbiological  
473 literature and remain unchanged from those used in Grant (1998b) and in Grant (1999).

474 **Appendix H: Inorganic N transformations**

475 **Mineralization and immobilization of NH<sub>4</sub><sup>+</sup> by all microbial populations**

476            Each functional component ( $j$ ) ( $j$  = labile or resistant) of each microbial  
477    population ( $m$ ) ( $m$  = obligately aerobic bacteria, obligately aerobic fungi, facultatively  
478    anaerobic denitrifiers, anaerobic fermenters plus H<sub>2</sub>-producing acetogens, acetotrophic  
479    methanogens, hydrogenotrophic methanogens and methanotrophs, NH<sub>4</sub><sup>+</sup> and NO<sub>2</sub><sup>-</sup>  
480    oxidizers, and non-symbiotic diazotrophs) in each substrate-microbe complex ( $i$ ) ( $i$  =  
481    animal manure, coarse woody plant residue, fine non-woody plant residue, particulate  
482    organic matter, or humus) seeks to maintain a set C:N ratio by mineralizing NH<sub>4</sub><sup>+</sup> [H1a]  
483    or by immobilizing NH<sub>4</sub><sup>+</sup> [H1b] or NO<sub>3</sub><sup>-</sup> [H1c]. Provision is made for C:N ratios to rise  
484    above set values during immobilization, but at a cost to microbial function. These  
485    transformations control the exchange of N between organic and inorganic states.

486    **Oxidation of DOC and reduction of O<sub>2</sub> by heterotrophs**

487            Constraints on heterotrophic oxidation of DOC imposed by O<sub>2</sub> uptake are solved  
488    in four steps:  
489    1) DOC oxidation under non-limiting O<sub>2</sub> is calculated from active biomass and DOC  
490    concentration [H2],  
491    2) O<sub>2</sub> reduction under non-limiting O<sub>2</sub> is calculated from 1) using a set respiratory  
492    quotient [H3],  
493    3) O<sub>2</sub> reduction under ambient O<sub>2</sub> is calculated from radial O<sub>2</sub> diffusion through water  
494    films of thickness determined by soil water potential [H4a] coupled with active uptake  
495    at heterotroph surfaces driven by 2) [H4b]. O<sub>2</sub> diffusion and active uptake is  
496    population-specific, allowing the development of more anaerobic conditions at  
497    microbial surfaces associated with more biologically active substrates. O<sub>2</sub> uptake by

498 heterotrophs also accounts for competition with O<sub>2</sub> uptake by nitrifiers, roots and  
499 mycorrhizae,

500 4) DOC oxidation under ambient O<sub>2</sub> is calculated from 2) and 3) [H5]. The energy yield  
501 of DOC oxidation drives the uptake of additional DOC for construction of microbial  
502 biomass ( $M_{i,h}$ ) according to construction energy costs of each heterotrophic population  
503 [H7-H13] in Grant and Pattey (2003). Energy costs of denitrifiers are slightly larger  
504 than those of obligate heterotrophs, placing denitrifiers at a competitive disadvantage  
505 for growth and hence DOC oxidation if electron acceptors other than O<sub>2</sub> are not used.

506 **Oxidation of DOC and reduction of NO<sub>3</sub><sup>-</sup>, NO<sub>2</sub><sup>-</sup> and N<sub>2</sub>O by denitrifiers**

507 Constraints imposed by NO<sub>3</sub><sup>-</sup> availability on DOC oxidation by denitrifiers are  
508 solved in five steps:

509 1) NO<sub>3</sub><sup>-</sup> reduction under non-limiting NO<sub>3</sub><sup>-</sup> is calculated from a fraction of electrons  
510 demanded by DOC oxidation but not accepted by O<sub>2</sub> because of diffusion limitations  
511 [H6],

512 2) NO<sub>3</sub><sup>-</sup> reduction under ambient NO<sub>3</sub><sup>-</sup> is calculated from 1) [H7],

513 3) NO<sub>2</sub><sup>-</sup> reduction under ambient NO<sub>2</sub><sup>-</sup> is calculated from demand for electrons not met by  
514 NO<sub>3</sub><sup>-</sup> in 2) [H8],

515 4) NO<sub>2</sub><sup>-</sup> reduction under ambient NO<sub>2</sub><sup>-</sup> is calculated from demand for electrons not met by  
516 NO<sub>2</sub><sup>-</sup> in 3) [H9],

517 5) additional DOC oxidation enabled by NO<sub>x</sub> reduction in 2), 3) and 4) is added to that  
518 enabled by O<sub>2</sub> reduction from [H5], the energy yield of which drives additional DOC  
519 uptake for construction of  $M_{i,n}$ . This additional uptake offsets the disadvantage  
520 incurred by the larger construction energy costs of denitrifiers.

521     **Oxidation of NH<sub>3</sub> and reduction of O<sub>2</sub> by nitrifiers**

522         Constraints on nitrifier oxidation of NH<sub>3</sub> imposed by O<sub>2</sub> uptake are solved in four  
523         steps:

524         1) substrate (NH<sub>3</sub>) oxidation under non-limiting O<sub>2</sub> is calculated from active biomass and  
525         from NH<sub>3</sub> and CO<sub>2</sub> concentrations [H11],

526         2) O<sub>2</sub> reduction under non-limiting O<sub>2</sub> is calculated from 1) using set respiratory  
527         quotients [H12],

528         3) O<sub>2</sub> reduction under ambient O<sub>2</sub> is calculated from radial O<sub>2</sub> diffusion through water  
529         films of thickness determined by soil water potential [H13a] coupled with active  
530         uptake at nitrifier surfaces driven by 2) [H13b]. O<sub>2</sub> uptake by nitrifiers also accounts  
531         for competition with O<sub>2</sub> uptake by heterotrophic DOC oxidizers, roots and  
532         mycorrhizae,

533         4) NH<sub>3</sub> oxidation under ambient O<sub>2</sub> is calculated from 2) and 3) [H14]. The energy yield  
534         of NH<sub>3</sub> oxidation drives the fixation of CO<sub>2</sub> for construction of  $M_{i,n}$  according to  
535         construction energy costs of each nitrifier population [H32-H34] in Grant and Pattey  
536         (2003).

537     **Oxidation of NO<sub>2</sub><sup>-</sup> and reduction of O<sub>2</sub> by nitrifiers**

538         Constraints on nitrifier oxidation of NO<sub>2</sub><sup>-</sup> imposed by O<sub>2</sub> uptake [H15-H18] are  
539         solved in the same way as are those of NH<sub>3</sub> [H11-H14]. The energy yield of NO<sub>2</sub><sup>-</sup>  
540         oxidation drives the fixation of CO<sub>2</sub> for construction of  $M_{i,o}$  according to construction  
541         energy costs of each nitrifier population.

542     **Oxidation of NH<sub>3</sub> and reduction of NO<sub>2</sub><sup>-</sup> by nitrifiers**

543           Constraints on nitrifier oxidation imposed by  $\text{NO}_2^-$  availability are solved in three  
544    steps:

545    1)  $\text{NO}_2^-$  reduction under non-limiting  $\text{NO}_2^-$  is calculated from a fraction of electrons  
546    demanded by  $\text{NH}_3$  oxidation but not accepted by  $\text{O}_2$  because of diffusion limitations  
547    [H19],

548    2)  $\text{NO}_2^-$  reduction under ambient  $\text{NO}_2^-$  and  $\text{CO}_2$  is calculated from step (1) [H20],  
549    competing for  $\text{NO}_2^-$  with [H18],

550    3) additional  $\text{NH}_3$  oxidation enabled by  $\text{NO}_2^-$  reduction in 2) [H21] is added to that  
551    enabled by  $\text{O}_2$  reduction from [H14]. The energy yield from this oxidation drives the  
552    fixation of additional  $\text{CO}_2$  for construction of  $M_{i,n}$ .

$LE_{ci} = L(e_a - e_{ci(T_{ci}, \psi_{ci})})/r_{ai}$	$LE$ from canopy evaporation	[B1b]
$LE_{ci} = L(e_a - e_{ci(T_{ci}, \psi_{ci})})/(r_{ai} + r_{ci}) - LE_{ci}$ from [B1b]	$LE$ from canopy transpiration	[B1c]
$H_{ci} = \rho C_p (T_a - T_{ci})/r_{ai}$	$H$ from canopy energy balance	[B1d]

$$r_{\text{cmini}} = 0.64 (C_b - C_i') / V_c'$$

$r_c$  driven by rates of carboxylation [B2a]

$$r_{ci} = r_{\text{cmini}} + (r_{\text{cmaxi}} - r_{\text{cmini}}) e^{(-\beta \psi_i)}$$

$r_c$  vs. diffusion [B2b]

$$r_{ai} = \{(\ln((z_u - z_{di})/z_{ri})^2 / (K^2 u_a)\} / (1 - 10 Ri)$$

$r_a$  driven by windspeed, surface [B3a]

$$Ri = \{g (z_u - z_{ri}) / (u_a^2 T_a)\} (T_a - T_c)$$

$r_a$  adjusted for stability vs. [B3b]

$$\psi_i = \psi_{ci} - \psi_{\pi i}$$

buoyancy [B4]

## Root and mycorrhizal water uptake

$$U_{wi} = \sum_l \sum_r U_{wi,r,l}$$

[B5]

$$U_{wi,r,l} = (\psi_{ci}' - \psi_{sl}') / (\Omega_{si,r,l} + \Omega_{ri,r,l} + \sum_x \Omega_{ai,r,l,x})$$

$U_w$  along hydraulic gradient [B6]

$$\psi_{ci}' = \psi_{ci} + 0.01 z_{bi}$$

[B7]

$$\psi_{sl}' = \psi_{sl} - 0.01 z_l$$

[B8]

$$\Omega_{si,r,l} = \ln\{(d_{i,r,l}/r_{i,r,l}) / (2\pi L_{i,r,l} K_{ri,r,l})\} \theta_{wl}/\theta_{pl}$$

[B9]

$$\Omega_{ri,r,l} = \Omega_{ri,r}/L_{i,r,l}$$

[B10]

$$\Omega_{ai,r,l,x=1} = \Omega_{ai,r} z_l / \{n_{i,r,l,1} (r_{i,r,l,1} / r_{i,r,l}')^4\} + \gamma \Omega_{ai,r} z_{bi} / \{n_{i,r,l,1} (r_{bi} / r_{b,i}')^4\} \sum_{i,r,l} (M_{i,r,l}) / M_{i,r,l}$$

[B11]

$$\Omega_{ai,r,l,x=2} = \Omega_{ai,r} (L_{i,r,l,2} / n_{i,r,l,2}) / \{n_{i,r,l,2} (r_{i,r,l,2} / r_{i,r,l}')^4\}$$

[B12]

$$\delta L_{i,r,l,1} / \delta \alpha = \delta M_{i,r,l,1} / \delta v_r / \{\rho_r (1 - \theta_{p,r}) (\pi r_{i,r,l,1}^2)\}$$

[B13]

## Canopy water potential

$$(e_a - e_{i(T_{ci})}) / (r_{ai} + r_{ci}) [B1] = \sum_l \sum_r (\psi'_{ci} - \psi'_{si}) / (\Omega_{si,r,l} + \Omega_{ri,r,l} + \sum_x \Omega_{ai,r,l,x}) + X_{ci} \delta \psi_{ci} / \delta t$$

[B14]

$\psi_{ci}$  solved when transpiration from [B1-B4] (LHS) equals uptake from [B5-B13] + change in storage (RHS)

### Surface water flux

$$Q_{rx(x,y)} = v_{x(x,y)} d_{mx,y} L_{y(x,y)}$$

2D Manning equation in  $x$  (EW) [D1]

$$Q_{ry(x,y)} = v_{y(x,y)} d_{mx,y} L_{x(x,y)}$$

and  $y$  (NS) directions

$$d_{x,y} = \max(0, d_{w(x,y)} + d_{i(x,y)} - d_{s(x,y)}) d_{w(x,y)} / (d_{w(x,y)} + d_{i(x,y)})$$

surface water depth [D2]

$$v_{x(x,y)} = R^{0.67} s_{x(x,y)}^{0.5} / z_{r(x,y)}$$

runoff velocity over E slope [D3]

$$v_{y(x,y)} = R^{0.67} s_{y(x,y)}^{0.5} / z_{r(x,y)}$$

runoff velocity over S slope

$$v_{x(x,y)} = -R^{0.67} s_{x(x,y)}^{0.5} / z_{r(x,y)}$$

runoff velocity over W slope

$$v_{y(x,y)} = -R^{0.67} s_{y(x,y)}^{0.5} / z_{r(x,y)}$$

runoff velocity over N slope

$$\Delta(d_{w(x,y)} A_{x,y}) / \Delta t = Q_{r,x(x,y)} - Q_{r,x+1(x,y)} + Q_{r,y(x,y)} - Q_{r,y+1(x,y)} + P - E_{x,y} - Q_{wz(x,y,I)}$$

2D kinematic wave theory for overland flow [D4]

$$R = s_r d_m / [2(s_r^2 + 1)0.5]$$

wetted perimeter [D5a]

$$s_{x(x,y)} = 2abs[(Z + d_s + d_m)_{x,y} - (Z + d_s + d_m)_{x+1,y}] / (L_{x(x,y)} + L_{x(x+1,y)})$$

2D slope from topography and pooled surface water in  $x$  (EW) [D5b]

$$s_{y(x,y)} = 2abs[(Z + d_s + d_m)_{x,y} - (Z + d_s + d_m)_{x,y+1}] / (L_{y(x,y)} + L_{y(x,y+1)})$$

and  $y$  (NS) directions

$$LE_l = L (e_a - e_{l(T_l, \psi_l)})/r_{al}$$

evaporation from surface litter
