39 **Introduction**

40 The supporting information contains additional details on the methods used for this

41 study and additional description of specific results and analysis of the data used in this

42 study. This supporting information also contains data to validate the box model analysis

43 used in the study and additional results that support the findings of the paper.

44

45 **Text S1. Methods**

46 Text S1.1 Site Description

47 The Potomac River drains water from both Maryland and Virginia and forms the
48 border between these two states. The entire Potomac River basin has a total drainage of
49 approximately 38,000 km² and is comprised of 16% cropland, 12% Pasture, 55% forest,
50 5% water and wetlands, 10% urban, and 3% other (Boynton et al. 1995). The upper
51 Potomac is freshwater and drains rural and agricultural areas above Washington D.C.,
52 while the Potomac River Estuary begins as tidal freshwater and salinity starts to increase
53 30 to 50 km downriver (Jaworski et al. 1992). The upper Potomac River Basin is
54 classified as 48% forested, 38% agricultural, and 14% urban (Karrh et al. 2007).

55 Sources of both nitrogen to the Potomac River include wastewater treatment
56 effluent (e.g. the Blue Plains Wastewater Treatment Plant), urban and agricultural runoff,
57 and atmospheric deposition. For the entire Potomac, the sources above the fall-line are
58 11.3% point, 84.6% diffuse, while the sources below the fall-line are 76.7% point, 15.4%
59 diffuse, and 5.4% atmospheric (Boynton et al. 1995). The study by Jaworski et al. (1992)
60 indicates that for the upper Potomac River, total nitrogen (TN) inputs are 27.5%
61 atmospheric deposition, 42.65% animal waste, 11.6% fixation and adsorption, 16%
62 fertilization, and 2.16% wastewater. The N outputs include 17.2% from river export,
63 17.1% from crop harvest, and 65.6% from other sinks and storage. Boynton et al. (1995)
64 also estimates that internal losses of TN for denitrification rates above the fall-line are
65 5.5% point, 16.3% diffuse of total inputs and losses, while the sources below fall-line are
66 19.9% point, 19.6% diffuse of inputs and losses.

67

68 Text S1.2 Water Sampling and Analysis

69

70 Three sets of routine sampling along the Lower Potomac were carried out (See
71 Figure 1). First, surface water was collected by small boat during seven separate months
72 between September 2009 through January 2011 above and below the Blue Plains
73 Wastewater Treatment Plant outfall (within 12 km). On each small boat cruise, 3-5
74 samples were collected longitudinally within 6 km above the wastewater outfall, one
75 sample was collected in the estuary at the Blue Plains effluent outfall, and 4-6 samples
76 were collected longitudinally within 12 km below the outfall. Monthly effluent samples
77 were also taken from the wastewater treatment plant before emptying into the estuary.
78 Second, monthly surface water samples were collected from nine Maryland Department
79 of Natural Resources sampling stations, located longitudinally down the Potomac River
80 Estuary, all the way to the Chesapeake Bay (from April 2010 to March 2011). Thirdly,
81 there were two larger multi-depth sampling cruises from 24 sampling stations along the
82 entire Lower Potomac River Estuary (August 2010 and May 2011). Samples were taken
83 at surface, middle and bottom depths during these two larger intensive sampling cruises.
84 See Table S1 for site coordinates for the sampling stations.

85 At each sampling location, a 1-liter plastic amber HPDE bottle (cleaned in 10%
86 HCl and distilled water) was used to take estuarine water samples. The surface water
87 samples were collected using a pump and hose on the boat at 0.5-meter depth. The 1-liter
88 bottle was then stored in a cooler, on icepacks until returning to the lab, where water was
89 stored in the refrigerator, until filtered within 24 hours.

90 Water was filtered through 47 mm/0.45 μ m glass fiber filter. The filtered water
91 was then partitioned into two bottles: one 30 ml Nalgene bottle, one 60 mL glass amber

92 Quorpak bottle. The 30 mL Nalgene bottle was frozen and saved for nitrate isotope
93 analysis. The 60 mL amber bottle was stored in a refrigerator (at 4°C), to be analyzed for
94 fluorescence within 3-weeks. For quality assurance, blank samples and replicates were
95 taken. The concentration of all total and dissolved forms of N, P, C were measured by
96 Nutrient Analytical Services Laboratory (NASL) at Chesapeake Biological Laboratory
97 (CBL).

98

99 Text S1.3 Salinity vs. Nitrate Concentration and Isotope Mixing Plots

100 The following equations from (Middelburg and Nieuwenhuize 2001) were used
101 for calculating the mixing lines. End member values for these equations were based on
102 the salinity, nitrate concentration, and nitrate isotope values found at the furthest up-
103 estuary sampling station and furthest down-estuary sampling station (Table S2).

104

105
$$S = f \times Sm + (1 - f) \times Sr \quad (1)$$

106

107
$$f = \frac{S - Sr}{Sm - Sr} \quad (2)$$

108

109
$$N = f \times Nm + (1 - f) \times Nr \quad (4)$$

110

111
$$\delta^{15}N = \frac{(\delta^{15}Nm \times f \times Nm + \delta^{15}Nr \times (1-f) \times Nr)}{N} \quad (5)$$

112

113 Where,

114 S = salinity of sample

115 S_r = salinity of freshwater endmember
116 S_m = Salinity of marine endmember
117 f = seawater fraction
118 N = Nitrate concentration of sample
119 ^{15}N = ^{15}N nitrate of the sample
120 $^{15}N_r$ = ^{15}N nitrate of freshwater endmember
121 $^{15}N_m$ = ^{15}N nitrate of marine endmember
