## Supplementary Methods

Methods S1. General additive model for quantifying LAI variation through time.
We examined the total and temporal variation in LAI using several complementary indices: leaf area duration, seasonal LAI enlargement, and maximum LAI. These indices required characterization of the temporal variation in LAI, which describes the variation in the seasonal flushing and shedding of leaves. To do so, we fitted a generalized additive mixed model (GAMM). For each plot, we calculated the mean LAI for a given time-point. We then fitted a GAMM as follows:

$$
\begin{gathered}
L A I_{i j}=\beta_{0}+\alpha_{0 i}+f\left(\text { Day }_{i j}\right)+\varepsilon_{i j} \\
\alpha_{i} \sim N\left(0, S L^{2}\right)
\end{gathered}
$$

In this model, each LAI observation $i$ in each sampling location $j$ within a plot varies as a function of the Julian day (Day), with a random intercept ( $\alpha$ ) for each of the seven sampling locations within a plot. With this model, we were able to estimate the LAI values for a given Julian day each year for each treatment (Fig. S5). This in turn allowed us to obtain the Julian days in which LAI starts to increase (positive slope change) from the minimum and when it starts to decrease (negative slope change) after the maximum LAI.

## Supplementary Tables

TABLE S1. Plot size, focal species combination, and fertilization scheme ( kg ) for each fertilizer employed in the experiment. For each plot, we provide the stand species combination: Dalbergia retusa Hemsl. (DALRET), Enterolobium cyclocarpum (Jacq.) Griseb. (ENTCYC), Hymenaea courbaril L. (HYMCOU), Simarouba glauca DC. (SIMGLA), Swietenia macrophylla King. (SWIMAC), and Handroanthus impeteginosus (Mart. ex DC.) Mattos (TABIMP). Experimental treatment abbreviations go as follows: Control, Drought + Fertilizer (D+F), Drought (D), and Fertilizer ( F ).

| Plot ID | Treatment | Stand | Area (m²) | Basacote ${ }^{\circledR}$ Plus 3M | Osmocote ${ }^{\circledR}$ Plus |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | Control | HYMCOU-DALRET | 189.00 |  |  |
| 2 | D+F | HYMCOU-DALRET | 163.68 | 15.35 | 16.37 |
| 3 | Control | HYMCOU-SWIMAC | 180.00 |  |  |
| 4 | D+F | HYMCOU-SWIMAC | 134.68 | 12.63 | 13.47 |
| 5 | F | HYMCOU-TABIMP | 180.00 | 16.88 | 18.00 |
| 6 | D | HYMCOU-TABIMP | 120.00 |  |  |
| 7 | D | HYMCOU-DALRET | 144.00 |  |  |
| 8 | F | HYMCOU-DALRET | 150.00 | 14.06 | 15.00 |

## Supplementary Figures

Fig. S1. Monthly rainfall (upper panel) and monthly temperature (lower panel) from a HOBO U30 weather station (Onset Computer Corporation, Bourne, MA, USA) located between 1.9 and 2.5 km from each plot at Estación Experimental Forestal Horizontes, Guanacaste, Costa Rica. From January 2016 to December 2017 and June 2020 to December 2020 the weather station was down, therefore for those two years we complemented our data using a nearby ( $\sim 14 \mathrm{~km}$ ) weather station in Santa Rosa National Park, Guanacaste, Costa Rica.

Fig. S2. Layout of the plantations (colored polygons) and the species combination stands (patterned polygons) at Estación Experimental Forestal Horizontes, Guanacaste, Costa Rica. From a total of 11 species, we selected six focal tree species: D. retusa Hemsl. (DALRET), E. cyclocarpum (Jacq.) Griseb. (ENTCYC), H. courbaril L.
(HYMCOU), S. glauca DC. (SIMGLA), S. macrophylla King. (SWIMAC), and H. impeteginosus (Mart. ex DC.)
Mattos (TABIMP). Non-patterned polygons represent additional combination of species not included in this study.
Dashed lines represent trails and black squares the location of the experimental plots.

Fig. S3. Diameter at breast height (DBH) for the plantation blocks selected to establish the rainfall manipulation and fertilization experiment in Northwestern Costa Rica. We selected six focal tree species to perform the experiment: $D$. retusa Hemsl. (DARE), E. cyclocarpum (Jacq.) Griseb. (ENTCY), H. courbaril L. (HYCO), S. glauca DC. (SIGLA), S. macrophylla King. (SWIMA), and H. impeteginosus (Mart. ex DC.) Mattos (TAIM). Significance obtained from species-specific analyses of variance to test the effect of the plantation block on the DBH.

Fig. S4. Soil particle size distribution for each experimental treatment in this study. Classification triangle according to the United States Department of Agriculture: clay (C), silty clay (SIC), sandy clay (SC), clay loam (CL), silty clay loam (SICL), sandy clay loam (SCL), loam (L), silty loam (SIL), sandy loam (SL), silty (SI), loamy sand (LS) and sand (S).

Fig. S5. Leaf area index mean values with $95 \%$ confidence intervals for each experimental treatment (Control, D+F: Drought + Fertilizer, D: Drought, F: Fertilizer) during the month of November. We found a significant year effect ( $\mathrm{F}=21.29$; d.f. $=3 ; \mathrm{p}<0.001$ ) because of tropical storm Nate, in which LAI decreased during November 2017 across all treatments. Letters represent multiple comparisons among years within experimental treatments from a Post-Hoc Tukey's honest significance difference test.

Fig. S7. Volumetric water content (SM) during the wet season for plots without a throughfall exclusion structure. Reported results from a two-way repeated-measures analysis of variance for the median wet season SM in four years. Lowercase letters stand significant differences within depths among years, and asterisks significant differences between depths within years. In both cases, we performed pairwise comparisons using a Post-Hoc Tukey's honest significance difference test.

Fig. S8. Soil pH and Olson extractable elements composition in the four experimental treatments: control, drought (D), drought+fertilizer ( $\mathrm{D}+\mathrm{F}$ ), and fertilizer (F). Reported results from a one-way analysis of variance for soils collected in 2021, after four years of nutrient additions. Lowercase letters stand for multiple comparisons among experimental treatments from a Post-Hoc Tukey's honest significance difference test.

Fig. S9. Relative growth rates (RGR) for plantation trees. Mean plots with their associated standard error show the interaction $(F=5.16, d . f .=1, \boldsymbol{p}=\mathbf{0 . 0 4 9 9})$ between the effects of fertilizer and drought treatments on nitrogen-fixing ( N -fixing) and non-nitrogen-fixing (Non-N-fixing) plant functional types.

Fig. S10. Diameter at breast height relative growth rates (RGR) over four years as a function of the experimental treatments: control, drought (D), drought+fertilization (D $+F$ ), and fertilization (F). Bar-plots showing the media, the standard deviation (error bars), and reported results from a two-way analysis of variance for each of the six focal tree species in the plantations.

Fig. S11. Demographic rates in a four-year interval (2016-2020) for understory individuals defined as the trees with a diameter at breast height ( DBH ) higher than 2.5 cm and lower than 7.5 cm as a function of the experimental treatments: control, drought (D), drought + fertilization $(D+F)$, and fertilization (F). We calculated the survival probability (a) and the mortality rate (b) as Condit et al. (2006). The recruitment rate (c) was calculated as the biomass of the total number of stems per plot area that recruited in the time interval.

Fig. S12. Productivity of reproductive structures as a function of the fertilization treatment. Results from a twoanalysis of variance with stand, plot, and sampling unit as random effects.

Fig. S13. Responses of leaf area index (LAI) metrics to drought and fertilization treatments. Mean plots showing the media, the standard error (error bars), and reported results from a two-way analysis of variance for each of the six LAI-derived metrics: maximum LAI ( $\operatorname{LAI}_{\text {max }}$ ), minimum LAI ( $\mathrm{LAI}_{\text {min }}$ ), leaf area enlargement (LAE), leaf area duration (LAD), leafless period (LLP), and the start of the leaf flushing (GSB).

Fig. S14. a) Responses of priming to two laboratory treatments using soils from each field treatments: control, fertilization (F), drought (D), and drought+fertilization ( $D+F$ ). b) Rewet priming response to drought led to higher priming of soil carbon in soils from drought treatment relative to soils with no drought treatment $(F-v=5.33, d . f$. $=$ $1, \boldsymbol{p} \boldsymbol{v}=\mathbf{0 . 0 4 9 7}$ ).

Fig. S15. Pearson correlation coefficients (R) and their associated significance for net primary productivity (NPP) as a function of each biomass flux for each experimental treatment.

Treatment Control O + F D O F
Fig. S16. Individual diameter at breast height relative growth rates (RGR) over four years as a function of the biomass loss due to mortality (Mortality biomass) for a given plot. Each dot represents an individual tree from the six focal species: D. retusa (DALRET), E. cyclocarpum (ENTCYC), H. impeteginosus (HANIMP), H. courbaril (HYMCOU), S. glauca (SIMGLA), and S. macrophylla (SWIMAC). Colors stand for experimental treatments such as control, drought + fertilization (DF), drought (DR), and fertilization (FR). Pearson's product-moment correlation (cor) and the associated significance level at: $\mathrm{p}>0.10(\mathrm{~ns}), \mathrm{p}>0.05(),. \mathrm{p}<0.05(*)$, and $\mathrm{p}<0.01\left({ }^{* *}\right)$.

Fig. S17. Bi-plot of the first two axes from a principal components analysis (PCA) describing the hydraulically saferisky ( PC 1 ) and the fast-slow ( PC 2 ) plant economic spectrum. Each dot represents a species from the tropical dry forest biome and colors correspond to the focal tree species in this study: D. retusa (DALRET), E. cyclocarpum (ENTCYC), H. impeteginosus (HANIMP), H. courbaril (HYMCOU), S. glauca (SIMGLA), and S. macrophylla (SWIMAC). Plant functional traits are defined as: leaf area (LA.cm2), specific leaf area (SLA), foliar nitrogen content (N.perc), wood density (WD), the water potential at $50 \%$ accumulation of leaf veins embolisms (P50.MPa), and the water potential at turgor loss point (TLP.MPA). Figure adapted from Vargas G. et al. (2021).
