Supplement of

Spatial and seasonal variability in volatile organic sulfur compounds in seawater and the overlying atmosphere of the Bohai and Yellow seas

Standard VSC gases with mixing ratios of 1 ppmv were bought from Beijing Minnick Analytical Instrument Equipment Center. Qualitative analysis was conducted by comparing the results with the retention times of the standards, and quantitative analysis was conducted by diluting the VSC standard gases to 1 ppbv and 5 ppbv using a 2202A dynamic dilution meter (Nutech, USA) and injecting different volumes of the diluted VSC standards into the GC using a gas-tight syringe. The VSC mixing ratios were calculated after calibration using standard gases. The VSCs standard curves were obtained as follows: (Fig. S1).

1. VSCs standard curves in spring

   (1) COS standard curve:

   The 5 ppbv standard gas was used, and the injection volumes were set as 5, 10, 20, 50, 100 mL. We use the standard gas mixing ratio * injection volume (25, 50, 100, 250, 500) as the X-axis, and the peak area detected as Y-axis. The mixing ratios of COS were calculated according to the peak area and correlative equation ($y = 4008.5x + 371580$). The injection volume of atmospheric gas is 200 mL.

   ![COS Standard Curve](image1.png)

   (2) DMS standard curve:

   The 1 ppbv standard gas was used, and the injection volumes were set as 0.2, 10, 20, 30, 50, 70 mL. We use the standard gas mixing ratio * injection volume (0.2, 10, 20, 30, 50, 70) as the X-axis, and the peak area detected as Y-axis. The mixing ratios of DMS were calculated according to the peak area and correlative equation ($y = 1976.6x - 11.126$).

   ![DMS Standard Curve](image2.png)

   (3) CS$_2$ standard curve:

   The 1 ppbv standard gas was used, and the injection volumes were set as 1, 2, 10, 20, 30, 50, 100 mL. We use the standard gas mixing ratio * injection volume (0.2, 10, 20,
30, 50, 70) as the X-axis, and the peak area detected as Y-axis. The mixing ratios of CS$_2$ were calculated according to the peak area and correlative equation ($y = 17125x + 98420$).

2. VSCs standard curves in summer
   (1) COS standard curve:

   \[ y = 1784.5x + 151031 \]
   \[ R^2 = 0.998 \]

   (2) DMS standard curve:

   \[ y = 437.58x + 7974.4 \]
   \[ R^2 = 0.9954 \]

   (3) CS$_2$ standard curve:
3. The schematics of the instruments were set up as follows:

Fig. S1 The VSCs standard curves and the apparatus diagram used for analysis of VSCs in atmosphere
Figure S2. Spatial distributions of nitrate, phosphate, and silicate in the surface water of the BS and YS in spring (a)-(c) and summer (d)-(f). The maps were plotted with Ocean Data View (ODV software) (Schlitzer, Reiner, Ocean Data View, odv.awi.de, 2023).
Figure S3. 12 h, 24 h, and 72 h backward trajectories of the air mass above stations B08, B47, B49 in spring and stations B49, B64, H09 in summer in the BS and YS of 2018.
Table S1. The pre-concentrator parameters of the three-stage cold trap.

</tr>
</tbody>
</table>

The parameterizations for COS, CS\(_2\) originate from De Bruyn et al. (1995), and the parameterization for DMS originates from Dacey et al. (1984). \( T^\circ \) is standard temperature (298.15 K).
