Figure C. Postglacial sea level change for different regions around the world (after Flemming *et al.*, 1998 and references therein). A rapid post 20 ka sea level rise is globally observed until *ca*. 8 ka when stabilized close to the present level. For Robinson Crusoe Island, some features interpreted as markers of the former sea level are also shown. Note that early Holocene supratidal flats (as inferred from 'teepee' structures) and sand layers with *Nerita* dated at *ca*. 8 ka are more than 70 m above the present sea level.
