I haven't been through this in detail, but on a quick read, this is a very nice study, and exactly the sort of thing that we need to help us figure out how complex our models need to be. My own (online as in-press) articles in Environmental Modelling and Software have highlighted this as an issue: our models have been getting more complex over decades, but as a community, we haven't really established whether this is improving their predictive capacity. This is a solid step in this direction. The trials including the effects of random noise were a good idea, and really help to differentiate improvements

in model skill from aparent improvements due to overfitting.
