10 Review of Tupek et al, 2014, BGD, 11, 8049–8084 CH<sub>4</sub> and N<sub>2</sub>O dynamics in the  
11 boreal forest–mire ecotone

12 General comments: This paper examines the production of CH<sub>4</sub> and N<sub>2</sub>O through a  
13 transitional landscape region commonly found in boreal environments. The paper uses  
14 the closed chamber method for 2-3 years over nine locations on an ecotone gradient.  
15 The paper finds minimal spatial patterns in N<sub>2</sub>O due to the generally low fluxes while  
16 CH<sub>4</sub> fluxes tended to follow a soil-wetness gradient. The authors did not detect any  
17 evidence for "hot moment" fluxes of either gas and also found relatively stable fluxes  
18 from year-to-year despite different wetness conditions in these years. I found the paper  
19 well put-together and interesting in its presentation of the data. The paper helps to fill  
20 a gap in current knowledge of these common transitional landscapes. It cites many  
21 interesting papers and helps to contextualize its results through a comparison to these  
22 other studies. I find the paper worth publishing in Biogeosciences after some revisions  
23 and additions to the content as detailed below.

24 **# Thank you!**

25 Suggestions: The paper would benefit from a stronger description of site differences,  
26 including pH and CN ratios for the different landscape units. It seems that the pH is  
27 not measured with each flux estimate, which is a pity in such a study. Especially with  
28 a discussion of microbial communities and the lag-time in response to changing water  
29 tables, pH can be a particularly useful indicator of CH<sub>4</sub> production potential. If you have  
30 such data for the sites (it is unlikely to change so greatly through the year) it would be  
31 nice to see it. Likewise some information about the site CN ratios would be useful for  
32 understanding both CH<sub>4</sub> and N<sub>2</sub>O fluxes.

33 **# We agree with the Referee that results on pH and C/N ratios would help  
34 the reader to understand individual site potential CH<sub>4</sub> and N<sub>2</sub>O fluxes. We  
35 analysed our remaining data and suggest extending the manuscript for pH of  
36 soil water solution and soil properties (bulk density and C/N ratios):**

37 *2 Material and methods*

38 *2.1 Study site characteristics*

39 *Page 8054, after Line 4*

40 **We measured pH during summer campaign 2005 from soil water data collected on all sites  
41 by suction-cup lysimeters. Three lysimeters were installed in 10 cm and one in 30 cm depth  
42 below the soil surface in each site. Detailed description of the lysimeters and sampling  
43 procedure can be found in Starr (1985). The pH was measured on the day of water sampling  
44 in the laboratory by pH meter equipped with a glass electrode. The mean acidity level of the**

1 sites of forest-mire ecotone was gradually increasing from pH 5.6 in uplands (CT) to 4.4 in  
 2 transitions (KR), whereas mires were less acid than transitions with pH 5.1 and 4.8 (VSR1  
 3 and VSR2 respectively) (Table 1). Collected soil water from 30 cm depth showed generally  
 4 higher pH than soil water pH at 10 cm depth. Three soil cores for each plot were taken in  
 5 July 2006 from the top soil (0-10 cm) in upland forests and from the two profile depths (0-10  
 6 cm, 10-30 cm) in forest mire transitions and in peatlands. The volume of samples was  
 7 measured before the oven drying at 70 °C to determine the bulk density. The bulk density  
 8 of the upper organic layer ranged from 0.24 gcm<sup>-3</sup> (KR) to 0.48 gcm<sup>-3</sup> (MT) and was  
 9 approximately half of the bulk density of the organic layer from 10-30 cm depth (mean of  
 10 transitions and mires 0.77 gcm<sup>-3</sup>) (Table 1). The C/N ratio was determined once for each plot  
 11 from the soil organic matter analysed by dry combustion with Leco CNS-1000 (Leco Corp.,  
 12 USA). The C/N ratio was wider in the 0-10 cm profile (mean 37) than in the 10-30 cm profile  
 13 (mean 27). The highest N content and lowest C/N ratio along the ecotone was found in  
 14 forest-mire transitions OMT+ and KgK (Table 1).

22 *3 Results*

23 *Page 8063, after Line 2*

24  
 25 **3.6 Effects of pH and soil properties on CH<sub>4</sub> and N<sub>2</sub>O flux**

26 **The site specific momentary CH<sub>4</sub> and N<sub>2</sub>O fluxes did not show significant correlation with**  
 27 **varying soil water pH (except for one correlation coefficient  $r = -0.45$ ,  $p = 0.02$  on MT for N<sub>2</sub>O**  
 28 **and pH at 10 cm). No correlation was found between CH<sub>4</sub> momentary data on the ecotone**  
 29 **level. Although, for the CH<sub>4</sub> data including group of upland forest and forest-mire**  
 30 **transitions (excluding mires) Pearson correlation between momentary CH<sub>4</sub> fluxes and soil**  
 31 **water pH was significant ( $r = -0.32$ ,  $p < 0.001$ ). Mean values of summer 2005 CH<sub>4</sub> of upland**  
 32 **forests and forest-mire transition were negatively correlated with mean pH (CH<sub>4</sub> = 129.35 –**

1 33.36\*pH,  $r^2 = 0.49$ , Fig. 8a). The ecotone  $N_2O$  fluxes of the summer 2005 pH campaign were  
 2 significantly correlated with pH ( $r = 0.174$ ,  $p = 0.004$ ). The mean  $N_2O$  values of sites  
 3 increased with mean pH ( $N_2O = -117.07 + 27.33*pH$ ,  $r^2 = 0.32$ , Fig. 8b). However, the post-  
 4 hoc Tukey differences of mean  $N_2O$  fluxes from forest floor for the pair-wise comparisons of  
 5 forest/mire types were not significant for 31 pairs and mean  $N_2O$  flux differences were  
 6 significant only for 5 pairs (KgK-CT, VSR1-KgK, VSR1-KR, VSR1-MT, VSR1-OMT, Figure 9).  
 7 We did not find significant correlation between site specific mean  $CH_4$  and  $N_2O$  flux and  
 8 bulk density and/or C/N ratio.

9

10 **Figure 8. Scatterplot between site specific mean pH and mean flux ( $\mu g m^{-2} g^{-1}$ ) of a)  $CH_4$  or b)**  
 11  **$N_2O$  of summer with intermediate moisture over the period of soil water sampling campaign**  
 12 **(July-September 2005). Error bars show standard error. The  $CH_4$  error bars for VSR1 and**  
 13 **VSR2 are not shown.**

1 *4 Discussion*

2 *4.1 CH<sub>4</sub> dynamics*

3 *added text on Page 8064, after Line 2 and before Line 3*

4 **Temporally water saturated soil layers of pristine forest-mire transitions had low CH<sub>4</sub>**  
5 **production partly due to highly acidic pH levels imposing physiological restrictions on soil**  
6 **microbial communities. Methanogenic activity in water saturated organic soils can be**  
7 **reduced by high acidity (e.g. Ye et al. 2012). Small momentary CH<sub>4</sub> emissions (Supplement**  
8 **Fig. 3a) observed in forest-mire transitions also indicated potential for occasionally higher**  
9 **production than consumption/oxidation. Beside microsite differences in soil saturation and**  
10 **microbial populations also plant communities (Fig. 1c) could play important role in**  
11 **explaining enhanced emissions (e.g. Saarnio et al., 1997, Riutta et al., 2007). For example,**  
12 **sedges through aerenchymatic transport interplay with microbes by providing recently**  
13 **photosynthesized carbon downwards and transporting CH<sub>4</sub> from microbial populations**  
14 **upwards (Alm et al., 1997).**  
15

16 *4.2 N<sub>2</sub>O dynamics*

17 *added text on Page 8066, after Line 19 and before Line 20*

18  
19 **Soil incubation studies under various moisture and temperature regimes (Pihlatie et al.,**  
20 **2004, Szukics et al., 2010) imply that our higher forest floor N<sub>2</sub>O emissions during typical**  
21 **summer 2005 than during dry summer 2006 (Supplement Fig. 3b) were probably induced by**  
22 **stimulated N turnover through the soil wetting and drying cycle under favorable**  
23 **temperature. During conditions with intermediate moisture (July-September 2005) we**  
24 **observed also mean N<sub>2</sub>O flux of dry pine forest significantly larger than paludified spruce**  
25 **forest (larger CT than KgK), whereas mean N<sub>2</sub>O flux of water saturated mire was larger than**  
26 **four sites (VSR1-KgK, VSR1-KR, VSR1-MT, VSR1-OMT) (Fig. 8, Fig. 9) . Therefore during**  
27 **fluctuating soil moisture, we could expect increased N<sub>2</sub>O fluxes of normally xeric (CT) and**  
28 **water saturated (VSR1) site due to stimulated nitrification (CT in rewetting phase, and VSR1**  
29 **in drying phase). During July-September 2005, CT and VSR1 sites were also least acid along**  
30 **the ecotone which could favor nitrification and consequently N<sub>2</sub>O emissions through**  
31 **denitrification (Regina et al., 1996, Ste-Marie and Pare´, 1999, Paavolainen et al., 2000).**  
32 **These studies reported that increasing of pH by rewetting could initiate nitrification. In**  
33 **contrast to less acid CT and VSR1, highly acid forest-mire transitions with widest range of**  
34 **water level fluctuations along the forest-mire ecotone ranked into a group of sites with**  
35 **lower N<sub>2</sub>O fluxes. Highly acid conditions prevent development of nitrifiers, substrate affinity**  
36 **and nitrification, even if ammonium is available (Ste-Marie and Pare´, 1999, Paavolainen et**  
37 **al., 2000). The fact that net nitrification of acid sensitive nitrifiers positively increases with**  
38 **forest floor pH, whereas acidification reduces it, suggests that nitrifiers in our sites were**  
39 **acid sensitive and not acid tolerant. The lack of nitrate renders denitrification potential to be**  
40 **negligible. Although, if nitrate would be present low pH would enhance N<sub>2</sub>O emissions due**  
41 **to inhibiting di-nitrogenoxide reductase and increasing N<sub>2</sub>O/N<sub>2</sub> ratio of denitrification (e.g.**  
42 **Weslien et al., 2009).**

43 *Page 8066, Lines 20, 21, 22 were reformulated*

44 **In pristine peatlands nitrification positively depended on pH and negatively on water level**  
45 **(Regina et al., 1996) in supply of nitrate for denitrification, as the main source of N<sub>2</sub>O**  
46 **emissions (Regina et al., 1996; Nykänen et al., 1995; Wray et al., 2007). Thus, during drying-**

1 rewetting periods as in July-September 2005 our sites could initiate short-term significant  
2 differences, but for the whole measurement period the lack of a statistically significant  
3 difference in N<sub>2</sub>O fluxes was probably due to low nitrification potential. Generally low pH  
4 and high C/N ratios of our forest floors suggest conditions of low nitrification potential.

31 The paper would benefit from a more complete time series of the fluxes for each site –  
32 something like Figure 2 for each gas flux (or another style of presenting this information  
33 – even the daily values). Otherwise it is hard to visualize how the time series may look,  
34 how seasonal and interannual shifts may or may not occur, etc., from only the fluxvariable  
35 relationships in Figs 4 and 7 and the overviews in Figs 3 and 5. This new figure  
36 could indeed replace or supplement figures 3 and 5. Alternatively such a presentation  
37 could be given as a supplemental on-line figure.

38 **# In order to visualise the seasonal and inter-annual shifts in CH<sub>4</sub> and N<sub>2</sub>O**  
39 **fluxes we provide the time series of daily momentary values (Supplement**  
40 **Fig. 3).**

### 13 **Anonymous Referee #2**

14 Received and published: 30 June 2014

15 This manuscript presents CH<sub>4</sub> and N<sub>2</sub>O fluxes measured along a forest-mire ecotone  
16 using the closed chamber technique. The manuscript closes an important knowledge  
17 gap as many studies on CH<sub>4</sub> and N<sub>2</sub>O fluxes have been conducted at typical forest  
18 sites and also in peatlands but I am solely aware of two published studies on CH<sub>4</sub>  
19 and N<sub>2</sub>O fluxes from a forest-mire transition zone. These two published studies were  
20 conducted in Canada. So this study would be the first from the European continent.  
21 It has been suggested before that such transition zones might be a hot spot of CH<sub>4</sub>  
22 emissions. This study could show at different meteorological conditions that this  
23 hypothesis is quite unlikely. The topic of the manuscript is well within the scope of the  
24 journal and is particularly suitable for the special issue: "Towards a full GHG balance  
25 of the biosphere". The paper meets a basic scientific quality, it is well structured. The  
26 applied closed chamber method is for sure the right one to achieve the goals of the  
27 study, results are presented in a clear way and discussion is comprehensive. I highly  
28 recommend that manuscript to be published in Biogeosciences Discussions.

29 **# Thank you!**

30 Minor suggestions:

31 Page 8059, Line 24

32 Unfortunately, neither Fig. 2 nor Fig 3 shows the correlation between CH<sub>4</sub> flux and ground  
33 water level, please include a new figure to show that correlation.

34 **# In response to similar requests of you and Referee#1 and in order to help  
35 visualize the relation between temperature, moisture and water table level  
36 dynamics (Fig. 2), and forest floor CH<sub>4</sub> and N<sub>2</sub>O fluxes (Fig. 3), we agree  
37 with adding Supplement Fig. 3 with the momentary CH<sub>4</sub> and N<sub>2</sub>O flux  
38 measurements (page 7 of this document).**

39  
40 Page 8061, Line 7

41 Just to clarify: which parameter shows the mean level of CH<sub>4</sub> fluxes in Table 1?

42 **The mean level of CH<sub>4</sub> fluxes of upland and transitional forests differed (Table 1, parameter  
43 "group bi"), ...**

44  
45 Page 8065, Line 21

46 change flurk to flark

47 **# changed to "flark"**

48 Page 8068, Line 2 Why do you put \_C in parenthesis?

49 **# parenthesis were deleted**

1 Figure 3: please explain in the labelling of the figure what does 3a) and 3b) show  
2 Figure 6: reference for that figure is missing in the text

3 **# The Fig.6 reference can be found on page 8062, line 14 and line 20.**

4  
5 General comment to figures: it might be better to use consistent  
6 designation for parts of one figure, either a), b) or right panel, left panel

7 **# to ensure consistency we changed designations for Fig. 6 and Fig. 7 to a)**  
8 **and b).**

9 **Anonymous Referee #3**

10 Received and published: 29 June 2014

11 General comments: The manuscript studies the question if CH<sub>4</sub> and N<sub>2</sub>O dynamics in  
12 transition zones between boreal forest and peatland are similar or different from those,  
13 considering that vegetation and hydrology change spatially and temporally between  
14 years. While carbon and nitrogen cycling in both boreal forests and peatlands are well  
15 studied, the transition zone has been less investigated. This can be an important factor  
16 for up-scaling to regional scales.

17 The authors report results from static chamber measurements along a 450m transect  
18 for the climatically different years 2004, 2005 and 2006. Statistical analyses (ANOVA,  
19 Tukey tests) are used to test differences between locations and years. Environmental  
20 controls are analyzed by fitting linear regression models to the flux data. Generally,  
21 substantial CH<sub>4</sub> fluxes only occur in the peatlands, while in forest soil and transition  
22 zones mostly CH<sub>4</sub> oxidation (neg. CH<sub>4</sub> fluxes) occurs. N<sub>2</sub>O emissions are small along  
23 the entire transect. The authors conclude that these transition areas are likely no hot  
24 spots for CH<sub>4</sub> and N<sub>2</sub>O emissions.

25 The paper is well written and fits into the scope of 'Biogeosciences'.

26 **# Thank you!**

27  
28 Minor comments: It looks like that the three forest-mire transition types (at least KgK  
29 and KR) are more similar in their CH<sub>4</sub> emissions to the upland forest than to the mires  
30 (N<sub>2</sub>O emissions are similarly low), even though soil organic matter content and soil  
31 moisture are higher than in the mineral forest soils.

32 The authors discuss that during the few occasions when the water table rises in the  
33 transition zones, a 'slow' response of the microbial communities prevent higher methane  
34 fluxes. I suggest to add vegetation characteristics in this discussion: e.g. sedges can both  
35 enhance methane production by supplying 'fresh' carbon substrate to methanogens as  
36 well as provide transport to the atmosphere via their aerenchyma.

37 **# In response to your comment on vegetation characteristics we suggest**  
38 **adding additional information on CH<sub>4</sub> flux of transitions.**

39 *4 Discussion*

40 *4.1 CH<sub>4</sub> dynamics, Page 8064 before Line 3*

41  
42 **Small momentary CH<sub>4</sub> emissions (Supplement Fig. 3) observed in forest-mire transitions**  
43 **also indicated potential for occasionally higher production than consumption/oxidation.**  
44 **Beside microsite differences in soil saturation and microbial populations also plant**  
45 **communities (Fig. 1c) could play important role in explaining enhanced emissions (e.g.**  
46 **Saarnio et al., 1997, Riutta et al., 2007). For example, sedges through aerenchymatic**  
47 **transport interplay with microbes by providing recently photosynthesized carbon**  
48 **downwards and transporting CH<sub>4</sub> from microbial populations upwards (Alm et al., 1997).**
