

1 **Author's Response**

2
3 *We thank the editor and the reviewers for their careful consideration of our manuscript and*
4 *for their helpful comments and suggestions. We adjusted our manuscript accordingly and*
5 *tried to clarify the issues that were pointed out. Please find below a point-by-point response*
6 *to all reviewer comments and a new version of the manuscript. Changes were marked in red*
7 *colour.*

8
9 **Response to Review #1 (RC C3776)**

10
11 p. 10032, ll. 7-9: please check and correct the sentence structure/brackets
12 *The sentence has been corrected as follows. "Tree litter in three natural (lower montane,*
13 *Ocotea and Podocarpus forests), two sustainably used (homegardens) and one intensively*
14 *managed (shaded coffee plantation) ecosystems was collected on a biweekly basis from May*
15 *2012 to July 2013."*

16
17 p. 10032, ll. 17,18: Unnecessary repetition, please delete the sentence
18 *The respective sentence was removed.*

19
20 p. 10035., l. 27: Zech et al. (2011) investigated the northern slopes of Mt. Kilimanjaro.
21 Better refer to Zech (2006, Palaeogeography, Palaeoclimatology, Palaeoecology 242,
22 303-312), who studied the southern slopes.
23 *Thank you very much for this suggestion, we changed the reference accordingly*

24
25 p. 10038, ll. 2ff: Not yet clear to me: did you check for seasonality visually or statistically?
26 *A visual approach was used as the basis for comparison and supported with some statistical*
27 *results. We added a new figure to clarify and visualize the results (see new Fig.3 attached).*
28 *We also changed the method of comparison to a more straight forward calculation based on*
29 *linear regression analysis.*

30
31 p. 10038, l. 6: delete "litter"
32 *Done.*

33
34 p. 10039, ll. 1,2: please check and correct, it should be the other way round.
35 *We corrected the paragraph as follows: "Due to the similar C and the increased N content,*
36 *the C:N ratio was significantly lower in managed ecosystems. It ranged from 16.9 (± 0.6) to*
37 *20.4 (± 0.6) in agroforestry systems and from 32.1 (± 0.4) to 44.9 (± 0.5) in natural forests."*

38
39 p. 10042, ll. 20-23. Concerning enhanced N-cycling on the southern slopes of Mt.
40 Kilimanjaro, please compare and include Zech et al. (2011, Isotopes in Environmental
41 Health Studies 47, 286-296) who found respective evidence based on $\delta^{15}N$.
42 *We included and discussed the suggested reference.*

43
44 Table 2: Concerning annual deposition of N and P via litterfall, compare and include
45 Schrumpf et al. (2006, Journal of Tropical Ecology 22, 77-89) in your respective result
46 or discussion chapter.
47 *The suggested reference was included in the discussion chapter 4.1.*

1 **Response to Review #2 (RC C4045 & RC C4470)**

2
3 *Dear Reviewer #2,*

4 *Thank you very much for your comments and suggestions. The review helped to enhance the*
5 *quality and improve the comprehensibility of our study. We adjusted our manuscript and tried*
6 *to clarify the issues that you pointed out.*

7
8 P.10033, l.13: What is ecosystem cycle??

9 *We changed the term to “ecosystem carbon and nutrient cycles” to clarify.*

10
11 P.10034, ll.4-6: Please check the order again!

12 *The order was changed as follows: (Zhou et al., 2006; Vasconcelos et al., 2008; Chave et al.,*
13 *2010; Celentano et al., 2011; González-Rodríguez et al., 2011; Fontes et al., 2014)*

14
15 P.10034, ll.9-12: Is this comments by Schrumpf et al. or other references? Please refer these
16 previous article correctly.

17 P.10034, ll.12-14: Please distinguish what you want know from well-known fact by previous
18 studies.

19 *Both of the above mentioned comments were adjusted as follows:*

20 *We changed the paragraph to: “Various studies in other ecosystems have shown that*
21 *artificial nutrient addition accelerates nutrient cycles (Allison and Vitousek, 2004; Forrester*
22 *et al., 2005; Homeier et al., 2012). It remains unclear how agricultural land use affects*
23 *nutrient balances and its interrelation to litter quantity, quality and the above- and*
24 *belowground element cycles in tropical (agro)ecosystems.”*

25
26 P.10034, l.22: Please add other information related to litterfall, such as biomass, history, scale
27 of each ecosystems.

28 *We added information or respective references on biomass and vegetation structure (Ensslin*
29 *et al, 2015). Because no specific land-use history is available for our sites, we added*
30 *reference for general land-use history of Mt. Kilimanjaro (Pabst, 2015).*

31
32 P.10034, l.23: Why did you choose this slope? At least, please describe general outline of the
33 unique field, Mt. Kilimanjaro and the feature of SW slope.

34 And 2nd RC: I understood why you choose the SW slope by your detail explanation, and/thus
35 I suppose that you'd had better to add such the useful information to this section.

36 *As requested, we added further information on the site selection and the integration in our*
37 *research group. The paragraph now reads as follows: “The study was conducted on the*
38 *south-western slope of Mt. Kilimanjaro (3°4'33"S, 37°21'12"E), Tanzania, along an elevation*
39 *gradient from 1 275 to 2 850 m a.s.l. Our study was part of the German Research Foundation*
40 *Project: Kilimanjaro ecosystems under global change. This interdisciplinary project provided*
41 *a number of long term research locations, plots, data and facilities along the south-western*
42 *slope of Mt. Kilimanjaro. Six research sites were selected according to the joint study design.*
43 *Each is representing either a typical tropical montane forest zone or a representative land-*
44 *use class of the region.”*

45
46 P.10035, ll.22-24: I suppose that this paragraph is suited in not here but in Introduction,
47 because this point is one of the strong points in your research.

48 *As you suggested, the paragraph was added to the introduction.*

1 P.10036, l.1: How many??
2 *Within each ecosystem, 10 litter traps (1m², 1mm mesh size) were installed as replicates*
3 *along two 100m transects (5 per transect). Due to the areal structure of one of the*
4 *homegardens (HOMb), the number of litter traps had to be reduced and only five replicates*
5 *could be installed. To exclude undergrowth, net heights were set between 20 and 100cm*
6 *above ground.*
7
8 P.10038, ll.17-18: I suppose this results is insightful and/thus, you had better to show not only
9 this data but also total data, such as matrix.
10 *Thank you for pointing out this unclarity. Since Reviewer#1 was concerned about this*
11 *sentence as well, we and added a new figure to clarify and visualize the results (see new Fig.3*
12 *attached). We also changed the method of comparison to a more straight forward calculation.*
13
14 P.10039, l.13: There are some errors, for example use of tense here and there in this
15 paragraph. Please check your english before you submit revised version.
16 *The manuscript has been sent to a professional language correction. Additionally, we revised*
17 *this paragraph carefully with respect to the used tense.*
18
19 P.10041, ll.1-2: It is very difficult to conclude that and discuss from this result (table 2), I
20 cannot conclude and discuss as follows. If you want to demonstrate and discuss about this
21 feature, you have to show another clear results.
22 *We agree with your criticism here. We rephrased and corrected the sentence and added*
23 *respective parts to the discussion. The discussion is based on the visual interpretation of*
24 *Figure 2 and the percental increase of minimum to maximum litterfall. We added the*
25 *percentages to the results section 3.2: "In natural forests, peaks increased about 350% in*
26 *FLM, 300% in FOC and 450% in FPO." The discussion was adapted according to these*
27 *results.*
28
29 P.10052, Table 1: Judging from these information, it is quite difficult to divid effect of
30 elevation and land-use pattern in this study. You had better add other statistical analysis to
31 speculate each effect on litterfall.
32 *We agree with your comment and would have preferred to do so. However, with our limited*
33 *number of treatments (i.e. elevation levels and land-use types) we refrained from applying*
34 *more complex statistics here. Of course we would appreciate any suggestion to overcome this*
35 *issue. In the current manuscript, we pointed out this limitation to our study as part of the*
36 *discussion section. We further extended this part in the revised manuscript and add to the*
37 *methods section.*
38 *The main points are as follows: The elevation effect was evaluated only within the natural*
39 *forest ecosystems to exclude land-use effects. This still covers a gradient of ~900m and three*
40 *very interesting ecosystems. The effect of land use was statistically analyzed comparing one*
41 *homegarden (HOMb) and the lower montane forest (FLM). According to Hemp (2006) and*
42 *Mt. Kilimanjaro exhibits a strong ecological zonation. Both ecosystems are located in the*
43 *same altitudinal zone (i.e. lower montane) and were selected to represent the respective zone*
44 *of natural species composition (Ensslin et al., 2015). Therefore, we assume low elevation*
45 *related variability. COF and HOMA were further used as indicators for the strong effect of*
46 *land use practices that is overlaying elevation effects. We think that this is adequate to (at*
47 *least qualitatively) assess the effect of land use.*
48

13 Abstract

14 Litterfall is one of the major pathways connecting above- and belowground processes. The
15 effects of climate and land-use change on carbon (C) and nutrient inputs by litterfall are
16 poorly known. We quantified and analyzed annual patterns of C and nutrient deposition via
17 litterfall in natural forests and agroforestry systems along the unique elevation gradient of Mt.
18 Kilimanjaro.

19 Tree litter in three natural (lower montane, Ocotea and Podocarpus forests), two sustainably
20 used (homegardens) and one intensively managed (shaded coffee plantation) ecosystems was
21 collected on a biweekly basis from May 2012 to July 2013. Leaves, branches and remaining
22 residues were separated and analyzed for C and nutrient contents.

23 The annual pattern of litterfall was closely related to rainfall seasonality, exhibiting a large
24 peak towards the end of the dry season (August – October). This peak decreased at higher
25 elevations with decreasing rainfall seasonality. Macronutrients (N, P, K) in leaf litter
26 increased at mid elevation (2100 m a.s.l.) and with land-use intensity. Carbon content and
27 micronutrients (Al, Fe, Mn, Na) however, were unaffected or decreased with land-use
28 intensity.

1 ~~On the southern slope of Mt. Kilimanjaro, the annual pattern of litterfall depends on seasonal~~
2 ~~climatic conditions.~~ While leaf litterfall decreased with elevation, total annual input was
3 independent of climate. Compared to natural forests, the nutrient cycles in agroforestry
4 ecosystems were accelerated by fertilization and the associated changes in dominant tree
5 species.

7 **1 Introduction**

8 With their high biodiversity and importance for the global carbon (C) cycle, tropical forests
9 are often highlighted as ecosystems of specific research interest (Brown, 1993; Sayer et al.,
10 2011). Tropical forest ecosystems account for one third of the terrestrial net primary
11 production (NPP) (Saugier et al., 2001) and contain more than half of the world's terrestrial
12 species (Groombridge and Jenkins, 2002). Tropical forests also act as a net sink for CO₂
13 (FAO, 2010) and contain roughly 25% of the terrestrial biosphere C (Bonan, 2008).

14 Tree litterfall is one of the major pathways in C and nutrient cycles that connect above- and
15 belowground processes (Vitousek and Sanford, 1986). As an important and regular source of
16 nutrients and organic matter, litterfall has been well studied over the past decades (Vitousek,
17 1984; Meier et al., 2005; Carnol and Bazgir, 2013). Nonetheless, litterfall varies considerably
18 between ecosystems, depending on climate, tree species composition, stand structure and soil
19 fertility (Vitousek and Sanford, 1986). Elevation is strongly affecting these parameters in
20 montane ecosystems (Ensslin et al., 2015; Pabst et al., 2013) and is of particular importance
21 regarding potential ecosystem shifts through climate change (Beniston, 2003). Therefore, the
22 effect of elevation on litterfall is an important indicator for estimating future changes in
23 ecosystem cycles.

24 Land-use change affects numerous biological, chemical and physical factors as well as their
25 interactions, leading to a high complexity and unpredictability of anthropogenic effects on
26 ecosystem functions (Groffman et al., 2001). Especially the functioning of C and nutrient
27 cycles under natural and disturbed conditions is important to assess the overall impact of
28 anthropogenic land use on tropical forest ecosystems. As reviewed by Don et al. (2011), soil
29 organic matter decreases up to 30% by converting tropical forests to agricultural systems.
30 These effects might still be underrepresented in estimates of overall ecosystem C fluxes (de
31 Blécourt et al., 2013).

1 This underrepresentation is particularly relevant because deforestation and conversion to
2 intensive agriculture are common transformations in tropical regions and are projected to
3 remain a major issue in the future (Lewis, 2006). Between 2000 and 2005, forest cover in
4 Africa decreased by 11.5 million ha (Hansen et al., 2010) and this number is feared to further
5 increase (UCS, 2011). The deforestation rate in Tanzania, for example, is already one of the
6 largest in Africa (Fisher, 2010). In contrast to other tropical regions, it is mainly driven by
7 small-scale farming for regional food production. Moreover, there was a considerable
8 intensification of agricultural land use at Mt. Kilimanjaro within the last 50 years (Misana et
9 al., 2012).

10 Most of the recent research on nutrient cycling in tropical forest ecosystems has been
11 conducted in the Neotropics and Southeast Asia (Zhou et al., 2006; Chave et al., 2010;
12 Celentano et al., 2011; González-Rodríguez et al., 2011; Fontes et al., 2014; Vasconcelos et
13 al., 2008), while African forests, especially montane rainforests in East Africa, have received
14 much less attention (Schrumpf et al., 2006; Dawoe et al., 2010). Mt. Kilimanjaro offers the
15 possibility to investigate nutrients cycles and litterfall along an elevation gradient were soils
16 have a similar age and developed from the same parent material (Dawson, 1992). We are
17 aware of only one study that published data on nutrient cycling with partial focus on litterfall
18 in Mt. Kilimanjaro ecosystems (Schrumpf et al., 2006). ~~That study, along with v~~Various
19 studies in other ecosystems, have show~~ns~~ that ~~anthropogenic-artificial changes-nutrient~~
20 addition accelerate nutrient cycles (Allison and Vitousek, 2004; Forrester et al., 2005;
21 Homeier et al., 2012). It remains unclear how agricultural land use ~~and especially its~~
22 intensification affects nutrient balances and its interrelation to litter quantity, quality and the
23 above- and belowground element cycles in tropical (agro)ecosystems.

24 Our primary objective was to assess the effect of climate and of agricultural land use on
25 litterfall and nutrient and carbon cycles in the dominant ecosystems of Mt. Kilimanjaro.
26 Therefore, we (1) collected the annual litter deposition and examined the litterfall dynamics
27 throughout the year, (2) measured the annual C and nutrient return and (3) compared
28 differences between natural and managed ecosystems and address implications for the
29 ecosystem nutrient cycle.

30

1 2 Methods

2 2.1 Study site

3 The study was conducted on the south-western slope of Mt. Kilimanjaro (3°4'33"S,
4 37°21'12"E), Tanzania, along an elevation gradient from 1 275 to 2 850 m.a.s.l. Our study was
5 part of the German Research Foundation Project: Kilimanjaro ecosystems under global
6 change. This interdisciplinary project provided a number of long term research locations,
7 plots, data and facilities along the south-western slope of Mt. Kilimanjaro. Six research sites
8 were selected according to the joint study design.; eEach is representing either a typical
9 tropical montane forest ecosystemzone or a representative land-use class of the region (Table
10 1). Lower montane forest (FLM), *Ocotea* forest (FOC) and *Podocarpus* forest (FPO) are three
11 natural sites located in Kilimanjaro National Park with minor anthropogenic impact.
12 Nonetheless, illegal logging for firewood and building material may occur, especially in the
13 lower FLM areas (Lambrechts et al., 2002; Rutten et al., 2015). The vegetation and zonation
14 of these ecosystems was classified and described in detail by Hemp (2006a). Summarily,
15 FLM is dominated by *Macaranga kilimandscharica*, *Agauria salicifolia* and partly *Ocotea*
16 *usambarensis*, while at higher elevation *Ocotea usambarensis* prevails, accompanied by
17 *Cyathea manniana* (FOC). The forest above 2 800 m.a.s.l. is dominated by *Podocarpus*
18 *latifolius* together with *Prunus africana* and *Hagenia abyssinica* (FPO). Two Chagga
19 homegardens (HOMa, HOMb) represent a traditional form of sustainably managed
20 agroforestry with sporadic organic fertilization with manure and household waste (Fernandes
21 et al., 1986). Homegardens are m1500ultilayered agroforestry systems with *Musa* ssp. and
22 *Coffea* ssp. as dominant crops under remnant forest trees (e.g. *Albizia schimperiana*, *Cordia*
23 *africana*) and cultivated fruit trees (e.g. *Persea Americana*, *Grevillea robusta*)(Hemp, 2006b).
24 Shaded coffee plantation (COF) represented an intensively managed land-use type with
25 regular application of mineral fertilizers and pesticides. A detailed description of land-use
26 history of Mt. Kilimanjaro was given by Pabst (2015) and further information on
27 aboveground biomass and vegetation structure is available from Ensslin et al. (2015).

28 The climate at Mt. Kilimanjaro is characterized by a bimodal rainfall regime with a short
29 rainy season around November and a longer one from March to May (Hemp, 2006a). Mean
30 annual precipitation (MAP) varies depending on elevation and exposition between 1 336 mm
31 and about 3 000 mm per year (Table 1). Mean annual temperature (MAT) ranges from 9.8 °C
32 to 20.9 °C and monthly means vary around ± 3 °C.

1 The comparison of ecosystems and litterfall on Mt. Kilimanjaro is especially beneficial
2 because the soils have a similar age and developed from similar parent material over the last
3 0.2 to 2.3 Mio years (Dawson, 1992). These parent materials are formed by volcanic rocks
4 such as basalt, trachyte and olivine basalts. Soils are classified as Andosols with folic, histic
5 or umbric topsoil horizons with accordingly high C contents in the upper horizons (~~Zech et~~
6 ~~al., 2011~~[Zech 2006](#)), often underlain by C rich paleosol sequences (Zech et al., 2014). Water
7 extractable and microbial biomass C increase with elevations and decrease with management
8 intensity (Pabst et al., 2013).

9

10 **2.2 Sampling**

11 Within each ecosystem, 10 litter traps (1m², 1mm mesh size) were installed as replicates along
12 two 100m transects (5 per transect). Due to the areal structure of one of the homegardens
13 (HOMb), the number of litter traps had to be reduced and only five replicates could be
14 installed. To exclude undergrowth, net heights were set between 20 and 100cm above
15 ground.~~Ten litter traps (1m², 1mm mesh size) were installed as replicates along two 100 m~~
16 ~~transects within each ecosystem. To exclude undergrowth, net heights were set between 20 cm~~
17 ~~and 100 cm above ground. Due to the areal structure of one of the homegardens (HOMb), the~~
18 ~~number of litter traps had to be reduced and only five replicates could be installed.~~ Between
19 April 2012 and July 2013, litter was collected twice a month.

20 Litter samples were oven-dried for one week at 60 °C and then weighed. Within the two-week
21 sampling interval the weight loss by decomposition was presumed negligible. Litter was
22 manually sorted into leaves, branches (<2 cm in diameter) and a rest fraction containing
23 blossoms and fruits as well as unidentified materials. Wooden material >2 mm is too
24 persistent to be evaluated within the timescale of our study and was thus excluded from
25 analysis. Leaf litter samples were coarsely ground and stored in paper bags for further
26 analysis.

27

28 **2.3 Analyses of carbon and nutrient contents**

29 We expected leaves to contain most of the litter nutrients (Yang et al., 2004). Therefore,
30 nutrient analyses were limited to the leaf fraction. Leaf litter samples were bulked randomly

1 and divided into two subsamples from five nets per time step. Nutrient content of leaf litter
2 was analyzed from six sampling dates equally distributed over one year. In line with
3 Celentano et al. (2011) we refrained from seasonal subdivision because most nutrients show
4 low seasonal variation. A total number of 12 samples per ecosystem were fine ground and
5 analyzed for C and nutrient contents. C and N contents were determined with a dry
6 combustion automated C:N analyzer (Vario EL, Elementar). After a preparative pressure
7 digestion, inductively coupled plasma optical emission spectrometry (ICP-OES, Spectro
8 Analytical Instruments) was used to determine contents of major macro- (Ca, K, Mg, P, S)
9 and micro- (Al, Fe, Mn, Na) nutrients. All chemical analyses were conducted in the laboratory
10 of the Department of Soil Science of Temperate Ecosystems, University of Göttingen.

11

12 **2.4 Calculations and statistical analyses**

13 Annual litter deposition per ecosystem was calculated as the average from nets over one year
14 (June 2012 to May 2013). Monthly deposition rates were calculated assuming a constant
15 amount per day for each sampling interval. For missing values we assumed a linear behavior
16 of litterfall between the previous and the following date. Nutrient deposition was calculated as
17 the product of annual leaf deposition and mean nutrient content.

18 As our data do not meet the requirements for ANOVA and non-normal distribution must be
19 assumed (Shapiro-Wilk test, $p < 0.05$), we applied non-parametric statistics. Significant
20 differences were detected using the Kruskal-Wallis test with a Bonferroni correction at p -
21 level=0.05 (Katz, 2006). The presented data are means of 5 to 10 replications \pm standard
22 error (SE).

23 All statistical analyses were conducted in R 3.0.1 (R Core Team, 2013) using core and
24 agricolae (Mendiburu, 2014) packages as well as the ggplot2 package for data visualization
25 (Wickham, 2009).

26

1 3 Results

2 3.1 Annual amount of litterfall

3 The annual amount of total litterfall was independent of land use and elevation, whereas the
4 amount of leaf litter in natural forests decreased with elevation (Fig. 1). The total annual input
5 varied from 4.6Mg ha^{-1} in HOMA to 10.7Mg ha^{-1} in HOMb. Accordingly, HOMb had a
6 significantly higher total litterfall than HOMA as well as FOC and FPO.

7 Total litterfall was dominated by the portion of leaves, contributing between 61% (FPO) and
8 74% (HOMb). The annual value in FLM was significantly higher than in FPO (Fig. 1).
9 Deposition of branches and rest were on the same level for all sites: each constituted less than
10 30% of total litterfall.

11

12 3.2 Seasonal dynamics of litterfall

13 The seasonal patterns of litterfall were the same for natural and agroforestry systems if
14 compared on the closest elevation level. In forests at higher elevation the seasonality was less
15 pronounced and the peak values shifted from the end of the dry season towards the rainy
16 season (Fig. 2).

17 Similar to the annual litterfall, changes in monthly ~~litter~~-litterfall were determined by the
18 portion of leaves. Maximum values in homegardens, COF and FLM were recorded between
19 the mid- and late dry season (Fig. 2). A second smaller peak appeared in the second rainy
20 season around April. Within these peaks, monthly litterfall increased three- (HOMA) to nine-
21 fold (COF) in agroforestry systems. In natural forests, peaks increased about 350% in FLM,
22 300% in FOC and 450% in FPO. In FOC and FPO the first peak was delayed until November
23 or December and was extended because litterfall rates remained high in the short dry season
24 between January and March. Litterfall maxima within the year were positively related to
25 elevation ($r^2=0.74$, $p=0.028$ Fig. 3). Deposition patterns of branches were independent of
26 seasons, and peaks occurred erratically (Fig. 2). The deposition of the rest fraction did not
27 follow pronounced dynamics but the peaks tended to increase during the rainy seasons.

28

1 3.3 Nutrient contents and deposition

2 Agroforestry systems showed higher macronutrient content and deposition rates than natural
3 forests (Table 2). With increasing elevation in the natural forests, nine of eleven analyzed
4 nutrients followed a hump-shaped pattern with the highest content in FOC (2120 m a.s.l.) and
5 lower contents in FLM (1920 m a.s.l.) and FPO (2850 m a.s.l.) (Appendix Table A1).

6 The N, P, and S contents in leaves under agricultural land use were significantly higher
7 compared to those in natural forests (Fig. 34; Appendix). Potassium was enriched in the leaf
8 litter of managed ecosystems (7.4 to 15.8 mg g⁻¹) versus most natural forests (3.1 to 7.2 mg g⁻¹).
9 The contents of C, Al, Mg, Fe, and Ca were independent of land use. Due to the similar C
10 and the increased N content, the C:N ratio was significantly lower in managed ecosystems. It
11 ranged from 16.9 (± 0.6) to 20.4 (± 0.6) in ~~agroforestry systems~~ ~~natural forests~~ and from
12 32.1 (± 0.4) to 44.9 (± 0.5) in ~~natural forests~~ ~~agroforestry systems~~. Na and Mn contents were
13 lower under agricultural land use (Table 2).

14 The effect of land use on the annual nutrient deposition was buffered by the amount of
15 litterfall, but remained present. HOMB had the highest C and nutrient deposition (except for
16 Mn and Na) via litterfall compared to all other ecosystems (Table 2). The coffee plantation
17 also had significantly higher N, P, K, Fe, and Ca deposition than all natural forests. Due to
18 minimal litterfall in HOMA the annual nutrient deposition was low despite high concentrations
19 in leaves. The deposition of most macronutrients in HOMA was still higher or on the same
20 level as in natural forests. The Al and Na deposition was unaffected by land-use intensity.
21 Annual Mn deposition was significantly higher in natural forests than in managed sites.

22

23 4 Discussion

24 4.1 Litterfall characteristics

25 The amounts of litterfall in Mt. Kilimanjaro ecosystems were within the common range for
26 tropical mountain forests and followed a pronounced seasonality dependent on climatic
27 variations. The annual leaf litterfall (4.6-10.7 Mkg ha⁻¹) was also within the same range as at
28 various other tropical sites (Chave et al., 2010; Zhang et al., 2014). A previous study at Mt.
29 Kilimanjaro found similar amounts of fine litterfall (7.5 Mgha⁻¹) at an elevation of 2250 to
30 2350 m. a.s.l. (Schrumpf et al., 2006). Lisanetwork and Michelsen (1994) reported annual fine

1 litter production ranging from 5.0 Mg ha⁻¹ to 6.5 Mg ha⁻¹ in tree plantations and 10.9 Mg ha⁻¹ in
2 a natural forest in the Ethiopian highlands. Similar results were found for cacao plantations in
3 lowland humid Ghana where total litter ranged from 5.0 Mg ha⁻¹ to 10.4 Mg ha⁻¹ (Dawoe et al.,
4 2010). The portion of leaf litter commonly varies between 60% and 90% (Lisanework and
5 Michelsen, 1994; [Schrumpp et al., 2006](#), Zhou et al., 2006; González-Rodríguez et al., 2011).
6 Accordingly, leaf portions in Mt. Kilimanajro litterfall (60-75%) were at the lower end of
7 tropical forest values.

8 The factors affecting litterfall amounts are succession stage, tree age and dominant plant or
9 tree species (Barlow et al., 2007; Celentano et al., 2011). Varying management practices and
10 crops in homegardens may alter these factors. The heterogeneity of the traditional
11 agroforestry systems explains the low annual litterfall in HOMA. Compared to HOMb, there
12 were more banana ~~tree~~plants (*Musa* ssp.) in HOMA, which were manually cut as a
13 management practice and thus were not accounted for by our litter traps.

14 Litterfall peaks during the dry season are well documented in tropical forests and plantation
15 systems and mainly reflect drought stress (Okeke and Omaliko, 1994; Barlow et al., 2007;
16 Selva et al., 2007). A recent meta-analysis by Zhang et al. (2014) has shown that this
17 connection is a characteristic feature of tropical ecosystems. Leaf aging, caused by
18 photoinhibition, stomatal closure and subsequent leaf overheating, might lead to leaf shedding
19 at the end of the dry season (Röderstein et al., 2005). As a side effect, trees are preparing for
20 the upcoming season of highest net primary production. By contrast, the peaks during the
21 rainy season are the result of strong winds and thunderstorms (Dawoe et al., 2010; González-
22 Rodríguez et al., 2011). This explains the observed increase in peaks of branch and rest
23 deposition during wet months.

24

25 **4.2 Effects of elevation**

26 The Mt. Kilimanjaro forest ecosystems are characterized by the absence of a pronounced
27 trend of total annual litterfall with elevation. When the leaf fraction was compared separately
28 though, the annual deposition was significantly higher in FLM than in higher forests (FOC,
29 FPO) (Fig. 1). Leaf litter production is considered to depend on temperature and thus
30 decreases at higher elevations (Okeke and Omaliko, 1994; Zhou et al., 2006; Girardin et al.,
31 2010). Nonetheless, a series of other studies from various ecosystems also show no decrease

1 with elevation (Röderstein et al., 2005; Köhler et al., 2008). Within our elevation range of
2 ~900 m in natural forests, the percentages of leaf litterfall were too small to determine a
3 notable decrease of total litterfall with elevation. Sporadic sampling at higher elevations (data
4 not shown) indicated that a litterfall decrease would become apparent in ecosystems above
5 3000 m a.s.l.

6 Seasonal variability of leaf litterfall in the natural forests on Mt. Kilimanjaro ~~decreased with~~
7 followed a U shaped pattern with increasing elevation (Fig. 2). In tropical montane forests,
8 the seasonality of litterfall is generally low compared to tropical lowland forests (Chave et al.
9 2010). We observed the weakest seasonal variation in *Ocotea* forest in 2190 m a.s.l., featuring
10 the highest annual precipitation and least varying soil moisture conditions (Table 1). At FPO
11 (2850 m a.s.l.) seasonality increased again with lower MAP and an increasing temperature
12 limitation. Litter production ~~in~~at higher elevation was distributed over the warmer period
13 between October and May when canopy productivity is usually higher (Girardin et al., 2010).
14 This pattern is based on the dependency of litterfall seasonality on rainfall intensities as well
15 as temperatures (Zhou et al., 2006; Chave et al., 2010). Changes of seasonality patterns
16 occurred within 200 m elevation difference (FLM to FOC). This suggests that elevation
17 effects can easily overlay biome specific litterfall patterns and can contribute to the
18 explanation of variabilities in large scale data (Zhang et al., 2014).

19 We found no consistent effect of elevation on litter nutrient content within the agroforestry
20 systems (Appendix A1). This indicates a strong overlay of elevation effects by land-use
21 practices. ~~These strong effect of land use on the nutrient contents in leaf litter~~ enables
22 discussing the changes in contents along an elevation gradient only by comparing natural
23 forests with each other. Carbon and most nutrient contents in leaf litter followed a hump-
24 shaped pattern with elevation. This pattern is typical for other ecosystem properties along
25 montane elevation gradients (Kluge et al., 2006; Mölg et al., 2009). It is also present for MAP
26 at Mt. Kilimanjaro (Table 1) as well as for aboveground biomass (Ensslin et al., 2015). Pabst
27 et al. (2013) reported hump-shaped soil moisture curves and mirroring patterns for soil pH
28 from the same Kilimanjaro ecosystems. Both parameters control soil nutrient availability and
29 they are ~~no~~without a doubt also key factors for variations of nutrient uptake by plants and
30 consequently for the litter nutrient contents.

31

1 4.3 Effects of land use

2 The contents of most macronutrients in leaf litter of managed ecosystems were two to five
3 times higher than in natural forests. This suggests that the chemical composition of leaf litter
4 at Mt. Kilimanjaro was significantly altered by land use and the associated change of
5 dominant plant or tree species.

6 Especially for studying land-use effects it can be difficult to find adequate and comparable
7 sites. At Mt. Kilimanjaro there is nearly no natural forest below and no land use above 1800
8 m a.s.l. Given this limitation to our study design we will only discuss land-use effects that are
9 significant when compared on the closest elevation levels (FLM and HOMb). According to
10 Hemp (2006) Mt. Kilimanjaro exhibits a strong ecological zonation. FLM and HOMb are
11 both located in the same altitudinal zone (i.e. lower montane) and were selected to represent
12 the respective zone of natural species composition (Ensslin et al., 2015). Therefore, we
13 assume low elevation related variability. This assumption is also supported by the similar
14 litter peak seasonality in both ecosystems (Fig. 3) and that are at least two times stronger than
15 the largest elevation effects. Several studies from the tropics focus on nutrient contents in leaf
16 litter of agricultural plantations (Beer, 1988; Dawoe et al., 2010), tree plantations (Sharma
17 and Pande, 1989; Carnol and Bazgir, 2013) and natural forests (Dent et al., 2006; Lu and Liu,
18 2012). Some studies also compared tree plantations to natural forests (Lisanework and
19 Michelsen, 1994; Celentano et al., 2011). However, the results vary considerably between
20 study sites and are not directly comparable to each other. For example, the N content in litter
21 is higher in Ethiopian natural forests than in tree plantations (Lisanework and Michelsen,
22 1994), while the opposite results were recorded from Costa Rican sites (Celentano et al.,
23 2011). Independent from elevation, HomegardensHOM and coffee plantationsCOF at Mt.
24 Kilimanjaro had higher N contents and therefore lower C:N ratios in leaf litter than natural
25 forests (Fig. 34). Nitrogen is a limiting factor in tropical montane forests (Vitousek, 1984;
26 Fisher et al., 2013), and N-deprived plants usually have a high C:N ratio in litter (Chave et al.,
27 2010). We expect two processes to mitigate the natural N limitation. First, the introduction of
28 crops such as *Musa* ssp. and ~~coffee~~ (*Coffea* ssp.) affects the nutrient content of vegetation and
29 litter in general. Second, fertilization leads to higher N contents in plants and consequently in
30 leaf litter (O'Connell and Grove, 1993). As a result the annual N deposition by litterfall in
31 HOM and COF increased and N cycling in these ecosystems was enhanced. This is well in
32 line with Zech et al. (2011), who found evidence for accelerated N-cycling in the cultivated

1 | areas of Mt. Kilimanjaro. Fertilization with N and P also increases the content of other
2 macronutrients in leaf litter (O'Connell and Grove, 1993). This corresponds to our findings
3 because the content of most macronutrients in land-use ecosystems either increased or
4 remained on the same level compared to the natural forests. Specific micronutrient
5 fertilization can be ruled out in homegardens (Fernandes et al., 1986). Consequently,
6 micronutrients were either unaffected (Al, Fe) or decreased under managed conditions (Mn,
7 Na).

8

9 **4.4 Implications for ecosystem cycles**

10 The effects of land use and elevation on litterfall and nutrient contents also lead to two
11 specific implications for C and nutrient cycles at the ecosystem level. The first implication
12 can be drawn from the seasonal dynamics of litterfall. Litterfall peaks at the end of the dry
13 season promote an accumulation of particulate organic matter on the surface soil. This
14 accumulation entails increased microbial activity and mobilization of C and nutrients during
15 the following wet season (Sayer et al., 2007; Blagodatskaya et al., 2009). Several studies
16 reported a peak in freshly mobilized C and nutrients in the early wet season, increasing the
17 possibility of leaching or translocation to deeper soil layers (Qiu et al., 2005; Pabst et al.,
18 2013). As a consequence, an increased nutrient deposition via litterfall might not necessarily
19 result in higher nutrient availability, but may actually increase nutrient losses. The
20 investigated agricultural ecosystems at Mt. Kilimanjaro experience distinct climatic
21 seasonality and accumulate large amounts of litter at the end of dry season. This implies that
22 the nutrient cycles in these ecosystems are especially vulnerable to changes in vegetation
23 structure and species composition.

24 The altered nutrient deposition rates lead to the second implication regarding turnover rates
25 and C losses from soils. There is ambiguous information on the effects of single nutrient
26 addition and fertilization on the decomposition rates of leaf litter (Khan et al., 2007; Grandy
27 et al., 2013). While N or P addition alone might delay nutrient mobilization, decomposition is
28 generally accelerated by a higher macronutrient content (Allison and Vitousek, 2004; Debusk
29 and Reddy, 2005). In addition, Debusk and Reddy (2005) postulated that this acceleration is
30 independent of soil nutrient content. The abundant macronutrients in the litter of the
31 investigated agricultural ecosystems therefore imply an accelerated C and nutrient turnover in

1 the respective ecosystems. Easily available substrate is decomposed faster, and soil
 2 respiration (i.e. soil CO₂ efflux) is generally higher in soils of intensively managed versus
 3 natural ecosystems at Mt. Kilimanjaro (Mganga and Kuzyakov, 2014). Together with tillage
 4 and crop removal, this explains the lower C and N stocks in the topsoil of agroforestry
 5 systems compared to natural forests at Mt. Kilimanjaro (Table 1). As a consequence, the
 6 conversion of natural forests to perennial plantations or homegardens probably represents a
 7 source of atmospheric CO₂ despite their structural resemblance to natural forests.

8

9 **5 Conclusions**

10 At the southern slope of Mt. Kilimanjaro, the annual pattern of litterfall depends on seasonal
 11 climatic conditions. Seasonality at lower elevations leads to a distinct peak of litter production
 12 in the late dry season (August – October) that is less pronounced at higher elevations. Annual
 13 leaf litter production decreased at higher elevations due to lower temperatures and reduced
 14 primary production. Nonetheless, other litter components (branches and rest) mask this effect
 15 and total annual litterfall was independent of climate and land-use.

16 Conversion of natural forests to sustainably or intensively used agroforestry systems leads to
 17 direct (change of dominant species) and indirect (increased nutrient uptake after fertilization)
 18 enrichment of macronutrients in leaf litter. The change in litter quality reduces the C:N ratio,
 19 increases the C and nutrient turnover rates in soil and so, accelerates the ecosystem C and
 20 nutrient cycles. This is followed by decreased C stocks in agroecosystems, with consequences
 21 to their fertility and ecosystem vulnerability. This calls for considering these effects when
 22 addressing land-use change and evaluating the sustainability of agroforestry and plantation
 23 management.

24

25 **Appendix A**

26 Table A1. Nutrient content in leaf litter (\pm SE) from six ecosystems at Mt. Kilimanjaro,
 27 Tanzania. Superscript letters indicate significant differences between the sites (derived from
 28 Kruskal-Wallis Test; p-level \leq 0.05).
