### New estimates of direct N<sub>2</sub>O emissions from Chinese croplands from 1980 to 2007 using localized emission factors

**B. Gao<sup>1</sup>, X.T. Ju<sup>1</sup>, Q. Zhang<sup>1</sup>, P. Christie<sup>1,2</sup>, F.S. Zhang<sup>1</sup>**

<sup>1</sup> College of Resources and Environmental Sciences, China Agricultural University, Beijing 100193, China

<sup>2</sup> Agri-Environment Branch, Agri-Food and Biosciences Institute, Belfast BT9 5PX, UK.

We estimated the maximum and minimum emission factors of paddy fields using the original raw data and log- and cube root-transformed data, and the defined class interval according to the difference between the maximum and minimum and the number of classifications, here calculated in accordance with 10 groups. Linear interpolation was applied to calculate the values that cannot be found directly in the table of normal area according to accumulated frequency, and the last obtained  $t$  values ( $\bar{t} \pm \delta t$ ) were also used to deduce the origin value by the method of linear interpolation (Table S1). The average group value  $\pm$  standard error ( $t = \bar{t} \pm \delta t$ ) from the method of direct calculation with original data through equations (1) and (2) using the values in Table S1 were 1.0977 and 0.682, respectively, and the corresponding origin values as calculated by linear interpolation were 2.44% and 1.93%, respectively, so giving a mean of 2.18% with a standard error of 0.25%. The values of  $\bar{t} \pm \delta t$  from using log-transformed data were 0.3745 and -1.1608, and the corresponding values of as calculated by linear interpolation were -0.602 and -0.660, respectively, giving a mean of -0.631 and standard error of 0.029, and then converted into original values to give a mean of 0.23% with a standard error of 1.07%. The values of  $\bar{t} \pm \delta t$  from the cube root-transformed data were 0.7364 and -0.6966, and the corresponding values as calculated by linear interpolation were 0.953 and 0.533, respectively, giving a mean of 0.743 with a standard error of 0.350, and then converted into origin values to give a

mean of 0.41% with a standard error of 0.04%.

We used the same method to calculate the emission factors of uplands (Table S2). The values of  $\bar{t} \pm \delta t$  from the method of direct calculation using the original data were 1.1009 and -0.0893, respectively, and the corresponding original values as calculated by linear interpolation were 2.88% and 0.92%, respectively, giving a mean of 1.90% with a standard error of 0.98%. The values of  $\bar{t} \pm \delta t$  using log-transformed data were 0.3681 and -1.1235, and the corresponding values as calculated by linear interpolation were 0.334 and -0.543, respectively, giving a mean of -0.105 with a standard error of 0.439, and then converted into origin values to give a mean of 0.79% with a standard error of 0.36%. The values of  $\bar{t} \pm \delta t$  using cube root-transformed data were 0.7146 and -0.7706, and the corresponding value as calculated by linear interpolation were 1.215 and 0.817, respectively, giving a mean of 1.106 with a standard error of 0.279, and then converted into origin values to give a mean of 1.05% with a standard error of 0.02%.
