

Interactive comment on “Modeling the sensitivity of soil mercury storage to climate-induced changes in soil carbon pools” by O. Hararuk et al.

Anonymous Referee #2

Received and published: 3 October 2012

i did one of the initial quick reviews and get reminders ever since that i shall post my comments. here they are. i hope this of any help.

Interested in the impact of warming climate on Hg i accepted the review this manuscript after some hesitation. Being not a modeler and mainly focusing on aquatic environments i may therefore only judge accordingly and perhaps give another point of view. The manuscript is very well written and structured, and i had great pleasure reading it. The idea of linking TM cycles, especially Hg to changing climate is relatively new and the authors propose a novel approach. General comments: Their model is based on the assumption the Hg/C stable and accesses the impact of changes of 3 variables: temperature, precipitation and CO₂ on the soil carbon budget (which is already well described in the literature) and finally Hg. The authors explain in detail their approach on

C4457

which assumption their findings are based on. I have however 3 point to rise: 1-Even though Hg has been almost only been addressed as a global contaminant in the past century of research and this climate link is novel, the former should not be out-casted completely. The authors should also consider that surface soil has (surely) received anthropogenic Hg, which might result in elevated Hg/C ratios, e.g. archives of atmospheric deposition, such as ombrothrophic peat bogs, are commonly used to trace this. 2-A major flaw is that their major findings are backed-up by a single reference (Natali et al., 2008) and this is not a benchmark piece (3 citations). Better arguments are needed. 3-The manuscript diverges a bit from the figures. The model is thoroughly explained, but the spatial heterogeneity of the results is not addressed in details. References are still in Endnote style (I guess) and need to be checked.

Specific comments: Abstract P1119: GEOS-Chem model uses the top 15cm, why the difference? Introduction A bit too long to my taste. P2113: Hg is not a pollutant because of its atmospheric residence time P2119: put in order of magnitude P2120: add/check Streets et al., 2012 P2123: top predators and humans P3114: bound to P3120: positive correlation P412: remove stores P4112: remove highly P5111: remove across the contiguous U.S. Methods P1019-14: needs to be shortened Results and discussions P14115: duplicate P1515: replace continent by U.S. P1615: address anthropogenic Hg here P16117-21: better shown in a table P1711-9: too long and complicated to read, shorten P17113: end phrase with simulations. P17117: end phrase with precipitation. P17122: end paragraph here. P1814-9: this is a figure caption not a text P2011-16: address oxidation-reduction briefly P2119: results of... P23123: CO₂, CO₂... Conclusions P26122: go beyond and describe in detail the implication for the studies sub-areas. Fig 2: poor linear correlation, explain
