

Interactive comment on “Improved quantification of microbial CH₄ oxidation efficiency in Arctic wetland soils using carbon isotope fractionation” by I. Preuss et al.

Anonymous Referee #2

Received and published: 14 February 2013

This manuscript examines the influence of methane oxidation and diffusion on the isotope ratio of CH₄ emitted from polygonal tundra. The authors make the scientific argument that fractionation due to diffusion is not often measured and they show that it can have a considerable effect on the ¹³C-CH₄ of emitted CH₄, thus improving our understanding of sources and sinks of CH₄ in these environments. The paper is thorough and well written, and although I cannot say I am an expert in the field of isotopic fractionation and CH₄ oxidation, the arguments and data seem well organized and justifiable. The conclusions seem to flow directly from the data and I do not think they are overstating their case. The only two comments I have are the following. First, on page 17019, the authors do not consider the importance of anaerobic methane oxidation in

C8185

either the change in concentration or ¹³C of CH₄ with depth. What affect could anaerobic methane oxidation have on either of these patterns? Second, the discussion is repetitive (around pages 17019/20), and could be 'tightened up' a bit.
