Received and published: 21 December 2016

Response to referee's comments

We thank and greatly appreciate the thoughtful and constructive comments from Professor Ferrio Diaz. We have fully considered your comments in the revision and improved the manuscript (revised manuscript marked in red color).

General comments

In this work, Zhao et al. present an experimental study on the interactive effects of CO₂

C1

and water availability on instantaneous water-use efficiency (iWUE) and the carbon isotope composition (d13C) of leaf water-soluble organic matter (LWSOM). Although the study of the interaction between CO₂ and drought and its effects on d13C and iWUE is not new (Picon, Ferhi, & Guehl 1997), there is no clear consensus on the interpretation of d13C changes in response to increasing CO₂ (Schubert & Jahren 2012). In this context, the comprehensive dataset here presented may contribute to understand the limitations of d13C as a surrogate for iWUE, and to better predict the response of tree species to increasing CO₂, particularly in drought-prone environments. This is particularly relevant for the proper interpretation of long-term trends in d13C in relation to changes in water use efficiency, particularly in drought-prone environments, e.g. based on tree-ring records (Duquesnay et al. 1998; Saurer, Siegwolf, & Schweingruber 2004; Voltas et al. 2013), or from herbarium and sub-fossil material (Peñuelas & Azcón-Bieto 1992; Beerling 1996; Köhler et al. 2010). The experiment is well-designed and the data is generally well presented, although some details on the methodology are missing (see technical corrections). However, the manuscript requires some improvements, particularly on the interpretation of results.

Response: Thank you for the careful review and constructive comments. According your helpful suggestions, revisions throughout the whole article have been made and the results have been improved and supplemented with the related contents.

Specific comments

My main concern about the manuscript is that it relies on the assumption that the only source of divergence between gas-exchange iWUE and d13C of recent assimilates could be post-photosynthetic fractionation. Although this is likely to play a role, the authors should consider that what actually defines carbon isotope discrimination (D13C) is the CO₂ concentration in the chloroplast (C_c), not in the intercellular space, as used in the simplified equation of the Farquhar's model (Evans et al. 1986; Farquhar, Ehleringer, & Hubick 1989). Indeed, the difference between gas-exchange derived values and online measurements of D13C has been widely used to estimate C_i-C_c and

C2

mesophyll conductance for CO₂ (Le Roux et al. 2001; Warren & Adams 2006; Flexas et al. 2006; Evans et al. 2009; Flexas et al. 2012; Evans & von Caemmerer 2013). In this regard, changes in mesophyll conductance could be partly responsible for the observed variations, as it generally increases in the short term in response to elevated CO₂ (Flexas et al. 2007; Flexas et al. 2014), whereas it tends to decrease under drought (Flexas et al. 2004; Ferrio et al. 2012; Hommel et al. 2014; Théroux-Rancourt, Éthier, & Pepin 2014). Hence, the manuscript would be greatly improved by considering both post-photosynthetic fractionation and mesophyll conductance as potential sources of variation. With the data available, the authors may be able to estimate changes in mesophyll conductance, based on the Evans method, which can be adapted to recent assimilates (Pons et al. 2009). Even without alternative estimates for mesophyll conductance, this would provide a useful ground for a deeper discussion.

Response: Thanks for your relevant and helpful comments about our research. The consensus has been reached that the routine of CO₂ diffusion into photosynthetic site in plant includes two main procedures, which are CO₂ moving from ambient environment surrounding the leaf (C_a) to the sub-stomatic cavities (C_i) through stomata, and from there to the site of carboxylation within the chloroplast stroma (C_c) of leaf mesophyll. The latter diffusion is defined as mesophyll conductance (g_m) (Flexas et al., 2008; Evans et al. 2009). Moreover, g_m has been identified to coordinate with environmental variables at the faster rate than that of stomatal conductance (Galmés et al., 2007; Tazoe et al., 2011; Flexas et al., 2007). g_m as the important factor that could improve water use efficiency under drought pretreatment (Han et al., 2016). There has been a dispute how g_m responds to fluctuation of CO₂ concentration. Terashima et al. (2006) have confirmed that CO₂ permeable aquaporin, located in the plasma membrane and inner envelope of chloroplasts (Uehlein et al. 2008), could regulate the change of g_m.

The ¹³C fractionation of CO₂ from air surrounding leaf to sub-stomatic cavity may be simply considered (Eqn. 6), whereas the fractionation induced by mesophyll conduc-

C3

tance from sub-stomatic cavities to the site of carboxylation in the chloroplast cannot be neglected (Pons et al., 2009; Cano et al., 2014). As estimating the post-photosynthetic fractionation in leaf, carbon discrimination generated by mesophyll conductance must be subtracted from ¹³C fractionation from the site of carboxylation to cytoplasm before sugars transportation, estimated from the difference between $\delta^{13}C_{WSC}$ ($\delta^{13}C$ of water soluble compounds by carbon isotopic method) and $\delta^{13}C_{model}$ ($\delta^{13}C$ modeled from gas exchange measurement), which was closely associated with g_m. Consequently, considering your constructive suggestions, g_m in our study was determined based on the Evans method, which can be adapted to recent assimilates (Pons et al. 2009). And then we can estimate the variation of g_m under SWC × [CO₂] treatments. Related methods, results, discussions and conclusion of g_m have been added in the revised manuscript (see Page 6-7, lines 216-261, Page 8-9, lines 319-330 and 347-355, Page 10-11, lines 410-435 and Page 12, lines 473-475). Subsequently, it has been shown that mesophyll conductance and post-carboxylation fractionation both contribute to the ¹³C fractionation from the site of carboxylation to cytoplasm (the difference between $\delta^{13}C_{WSC}$ and $\delta^{13}C_{obs}$), which is derived from ¹³C fractionation following the carboxylation while photosynthate having not been transported to the twigs of plant in our study.

Technical corrections

In its present form, the title may suggest that instantaneous water use efficiency is changing because of post-carboxylation fractionation, which is clearly not the case. Besides, after considering the role of mesophyll conductance, post-carboxylation fractionation should not play such a major role in the title. An alternative might be "The interaction of CO₂ concentrations and water stress in semi-arid areas causes diverging response in instantaneous water use efficiency and carbon isotope composition". This leaves open the possibility to discuss both post-photosynthetic fractionation and mesophyll conductance as potential causes for the observed divergence.

Response: We thank referee and greatly appreciate the thoughtful and constructive comments. Following your suggestions, the title was changed as "The interaction of CO₂ concentrations and water stress in semi-arid areas causes diverging response in instantaneous water use efficiency and carbon isotope composition" in the revised manuscript, which can more comprehensively discuss both post-photosynthetic fractionation and mesophyll conductance as potential causes for the observed divergence.

In the abstract, lines 11-14: it seems that several concepts are mixed together here,

C6

trying to summarize everything in one sentence, but the result is unclear. I would recommend to split the ideas in shorter lines, and to try to go step by step in the argumentation line of the abstract.

Response: Based on your constructive recommendation, we rewrote this part as (starting on Lines 10-13 in the abstract):

"The ^{13}C fractionation may be generated through the transformation from photosynthate to sugars before transporting them outward the leaf. The influence of environmental conditions (i. e. CO_2 concentration and water stress) and their interactions on this fractionation have not yet been identified".

The number of replicates (saplings) per treatment is not given in the methods (however it is shown in the figures, $n=32$). Please add, and also specify the number of leaves measured/sampled per tree, number of gas-exchange measurements per leaf, etc.

Response: Considering your suggestions, we modified and specified the sampling and measuring process in gas-exchange measurements and the extractions of water soluble compound of leaves to read (starting on Page 4, Line 159-161 and on Page 5, Line 168-170, respectively):

"Four replicates were measured with each leaf and four leaves were chosen per tree in the gas-exchange measurement. There were two saplings ready for one orthogonal treatment ($[\text{CO}_2] \times \text{water stress}$)."

"After gas exchange measurements, recently-expanded, eight sun leaves were removed per tree of two species and two cultivated saplings per specie were replicated per treatment, and then were frozen immediately in liquid nitrogen."

In line 263 an attempt to quantify the so-called 'post-carboxylation fractionation' is given, but the methodology used is not described. As it is written, the sentence "When comparing WUE_{ge} and WUE_{cp} , the ^{13}C -depletion" is misleading, since it is not WUE calculated by the two methods what is compared here, but observed and modelled

C7

$\delta^{13}\text{C}$. I guess the value results from the difference between observed $\delta^{13}\text{C}$ and modelled $\delta^{13}\text{C}$ calculated from gas-exchange data, i.e. by reverting equations 3 and 4, however this is not explained in the methods.

Response: Thanks for your helpful comments. Consistent with your speculation and considering the effect of mesophyll conductance, the defined 'post-carboxylation' or 'post-photosynthesis' that can explain part of the ^{13}C fractionation from the site of carboxylation to cytoplasm before sugars transportation that is the difference between observed $\delta^{13}\text{C}$ of water soluble compounds from leaves and the modeled $\delta^{13}\text{C}$ calculated from gas-exchange, which in unmodified manuscript was not been explained in the methods, misleading that with the difference between WUE_{ge} and WUE_{cp} . Considering with your suggestions, we added the methodology of post-carboxylation in "2.4.1 The ^{13}C fractionation between the sub-stomatic cavities and the ambient environment" that reads (starting on Page 6, Line 209-215):

"Then the ^{13}C fractionation between the sub-stomatic cavities and the ambient environment (total ^{13}C fractionation) can be estimated by the observed $\delta^{13}\text{C}$ of water soluble compounds from leaves ($\delta^{13}\text{C}_{\text{WSC}}$) and the modelled $\delta^{13}\text{C}$ calculated from gas-exchange ($\delta^{13}\text{C}_{\text{model}}$). The $\delta^{13}\text{C}_{\text{model}}$ can be calculated from Δ_{model} from Eqn. (2). The Δ_{model} can be determined by Eqns. (3 and 4) as:

$$\Delta_{\text{model}} = (b-a)(1 - (1.6\Delta e \text{WUE}_{\text{ge}}) / C_a) + a \quad (7)$$

$$\delta^{13}\text{C}_{\text{model}} = (C_a - \Delta_{\text{model}}) / (1 + \Delta_{\text{model}}) \quad (8)$$

$$\text{Total } (\delta^{13}\text{C}) \text{ fractionation} = \delta^{13}\text{C}_{\text{WSC}} - \delta^{13}\text{C}_{\text{model}} \quad (9)."$$

"3.4 ^{13}C fractionation from the site of carboxylation to cytoplasm before sugars transportation" has been modified as (starting on Page 8, Line 307-318):

"We evaluated the total ^{13}C fractionation from the site of carboxylation to cytoplasm by gas exchange and $\delta^{13}\text{C}$ of water-soluble compounds from leaf measurements (Table 1), which can retrace ^{13}C fractionation before carboxylation transport to the twig. Com-

C8

paring $\delta^{13}\text{C}_{\text{WSC}}$ with $\delta^{13}\text{C}_{\text{model}}$ from Eqns. (4, 7 and 8), total ^{13}C fractionation of *P. orientalis* ranged from 0.0328‰ to 0.0472‰ which was smaller than that of *Q. variabilis* (0.0384‰ to 0.0466‰). The total fractionations of *P. orientalis* were magnified with soil wetting especially that was increased by 21.30%–42.04% at 35%–80% of FC from C400 to C800. Fractionation coefficients under C400 and C500 were amplified as SWC increased until 50%–60% of FC in *Q. variabilis*, whereas it was increased at 50%–80% of FC and decreased at FC under C600 and C800. Elevated $[\text{CO}_2]$ enhanced the average fractionation effect of *P. orientalis*, while those of *Q. variabilis* declined sharply from C600 to C800. Total ^{13}C fractionation in *P. orientalis* increased faster than did those of *Q. variabilis* with increased soil moisture."

"4.4 Post-carboxylation fractionation generated before photosynthate leaving leaves" was been improved as (starting on Page 11, Line 450-453):

"When comparing $\delta^{13}\text{C}_{\text{WSC}}$ with $\delta^{13}\text{C}_{\text{obs}}$, total fractionations of *P. orientalis* ranged from 0.0328‰ to 0.0472‰ less than that of *Q. variabilis* (from 0.0384‰ to 0.0466‰). Then total ^{13}C fractionation subtracted by fractionation derived from mesophyll conductance, post-photosynthetic fractionation occupied 75.30%-98.9% of total ^{13}C fractionation."

The conclusion of this manuscript need to be modified as (starting on Page 12, Line 465-468 and 475-479):

"The influence of mesophyll conductance on the difference of ^{13}C fractionation between the sub-stomatic cavities and the ambient environment need to be considered, while testing the hypothesis that the post-carboxylation will contribute to the ^{13}C fractionation from the site of carboxylation to cytoplasm before sugars transportation."

"Rising $[\text{CO}_2]$ and/or soil moistening generated increasing disparities between $\delta^{13}\text{C}_{\text{WSC}}$ and $\delta^{13}\text{C}_{\text{model}}$ in *P. orientalis*; nevertheless, the differences between $\delta^{13}\text{C}_{\text{WSC}}$ and $\delta^{13}\text{C}_{\text{model}}$ in *Q. variabilis* increased as $[\text{CO}_2]$ being less than 600 ppm and/or water stress was alleviated. Total ^{13}C fractionation in leaf was linearly

C9

dependent on g_s ."

Text in the legends of Figs. 2-5 could be larger. Since each panel is associated to one single species, they could be simplified by including the name of the species elsewhere in the figure, and using the symbols only for the CO_2 levels. The symbols for a given CO_2 level could be the same in all panels, regardless of the species (in this way, one legend would be enough for all the panels).

Response: Thanks for your constructive comments. Considering your suggestions, the legends of Figs. 2-5 were simplified in the revised manuscript. The symbols for CO_2 concentration of 400 ppm, 500 ppm, 600 ppm and 800 ppm were uniformly presented as C400, C500, C600 and C800 in sequence. One legend was shown in all panels of one Figure shown in Figs. 2-5 of revised manuscript.

In Figure 6 I would use the symbols to indicate CO_2 levels, as in the rest of figures. This would be useful to see whether the positive association between "fractionation" and g_s is linked with CO_2 or water availability.

Response: Thank you for suggestions about the graphic settings. According your consideration, we have redrawn the images of Figs. 7 and 8 in the revised manuscript, which could obviously illustrate the relationships between g_s/g_m and total ^{13}C fractionation. The legends of Figs. 7 and 8 were simplified. The symbols for CO_2 concentration of 400 ppm, 500 ppm, 600 ppm and 800 ppm were uniformly presented as C400, C500, C600 and C800 in sequence.
