1 **Abstract**

2 The origin of the N which contributes to the synthesis of N reserves of *in situ* forest
3 trees in autumn, and to the growth of new organs the following spring, is currently
4 poorly documented. To characterize the metabolism of various possible N sources
5 (plant N and soil N), six distinct 20 year-old sessile oaks were ¹⁵N labelled by
6 spraying ¹⁵NH₄¹⁵NO₃: (i) on leaves in May, to label the N pool remobilized in the
7 autumn for synthesis of reserves; (ii) on soil in the autumn, to label the N pool taken
8 up from soil; (iii) on soil at the beginning of the following spring, to label the N pool
9 taken up from soil in the spring. The partitioning of ¹⁵N in leaves, twigs, phloem,
10 xylem, fine roots, rhizospheric soil and microbial biomass was followed during two
11 growing seasons. Results showed a significant incorporation of ¹⁵N in the soil-tree
12 system; more than 30% of the administered ¹⁵N was recovered. Analysis of the
13 partitioning clearly revealed that in autumn, roots' N reserves were formed from
14 foliage ¹⁵N (73%) and to a lesser extent from soil ¹⁵N (27%). The following spring,
15 ¹⁵N used for the synthesis of new leaves came first from ¹⁵N stored during the
16 previous autumn, mainly from ¹⁵N reserves formed from foliage (95%). Thereafter,
17 when leaves were fully expanded, ¹⁵N uptake from soil during the previous autumn
18 and before budburst contributed to the formation of new leaves (60%).

21

22 **1. Introduction**

23 Tree carbon metabolism associated with photosynthesis, C allocation and
24 remobilization of C storage is well documented (Barbaroux et al., 2003; Dickson,
25 1989), but tree nitrogen metabolism is less known. Nevertheless, seasonal N cycling
26 is a determinant of plant fitness in perennials, particularly long-lived perennials such
27 as forest trees (Cooke and Weih, 2005). In early spring, trees' nitrogen demand for
28 growth can be satisfied either by uptake of external sources such as ammonium,
29 nitrate and organic N available from the soil (Gessler et al., 1998a), or by
30 remobilization of internal stores (Bazot et al., 2013; Coleman and Chen, 1993; Cooke
31 and Weih, 2005; El Zein et al., 2011b; Gilson et al., 2014; Millard, 1996; Taylor, 1967).
32 In many species, N remobilization for growth in spring occurs before utilization of N
33 taken up by roots, typically during the 20–30 days before the roots actively take up
34 N. These species include: deciduous species, such as *Quercus petraea* (El Zein et al.,
35 2011a), *Malus domestica* (Guak et al., 2003; Neilsen et al., 2001), *Populus*
36 *trichocarpa* (Millard et al., 2006), *Prunus avium* (Grassi et al., 2003), *Pyrus*
37 *communis* (Tagliavini et al., 1997) and *Sorbus aucuparia* (Millard et al., 2001);
38 marcescent/evergreen species, such as *Nothofagus fusca* (Stephens et al., 2001); and
39 coniferous evergreens, such as *Picea sitchensis* (Millard and Proe, 1993). In a few
40 species (e.g., *S. aucuparia*), remobilization has completely finished before any root
41 uptake of N occurs, even if trees are supplied with an adequate supply of mineral N
42 in the soil. In contrast, other species have been shown to begin taking up soil N
43 through their roots concomitantly with N remobilization. These include deciduous
44 *Juglans nigra* × *regia* (Frak et al., 2002), *Pyrus communis* (Tagliavini et al., 1997),
45 *Betula pendula* and evergreen *Pinus sylvestris* (Millard et al., 2001). All of these
46 studies were conducted on young trees or/and under controlled conditions. Few

47 studies have applied ^{15}N -labeled mineral fertilizer to larger, undisturbed trees
48 growing in the field (El Zein et al., 2011a), and even those only evaluated the
49 contribution of spring N uptake to leaf and twig growth, while the contribution of
50 stored N was indirectly estimated. However, in autumn, the process of N storage (N
51 translocation from leaves to sink compartments), which starts concomitantly with
52 leaf yellowing (Bazot et al., 2013), is associated with a stimulation of soil nitrogen
53 uptake (Gessler et al., 1998b; Jordan et al., 2012; Kim et al., 2009). In the present
54 study we proposed to investigate the contribution of N storage and that of N taken up
55 from soil during autumn and spring, to the development of new leaves of 20 year-old
56 sessile oaks in the field, after budburst during the following spring. Does soil N or
57 foliar N contribute most to the storage of N compounds in autumn? Does soil N or
58 stored N contribute most to the synthesis of new leaves in spring? Soil ^{15}N labelling
59 is a suitable tool to quantify autumn and spring uptake of N by roots. Labelling of
60 foliage allows quantification of N remobilized from leaves to reserve compartments.
61 During three distinct labelling campaigns, 3 x 2 distinct 20-year-old sessile oaks
62 received $^{15}\text{NH}_4^{15}\text{NO}_3$ applied to their foliage (May), or on adjacent soil (September
63 and March of the following year). ^{15}N partitioning in all tree-soil compartments, i.e.
64 leaves, twigs, trunk, roots, rhizospheric soil and microbial biomass, was analysed
65 regularly. The contribution of assimilated ^{15}N to storage and remobilization was
66 investigated.

67

68 **2. Materials and methods**

69 **2.1. Site description**

70 The experiment was conducted in an area of 20-year-old naturally regenerated oak in
71 the Barbeau forest (48°29'N, 02°47'E), 60 km southeast of Paris, France, at an

72 elevation of 90 m on a gleyic luvisol. The average air temperature is 10.5 °C and the
73 annual rainfall in this temperate location is 690 mm. Six 20-year-old sessile oaks
74 (*Quercus petraea* L.) were selected, their height ranged between 8 to 10 m and their
75 average diameter at breast height was 10 cm. In order to limit possible interference of
76 root cutting with nitrogen allocation, at least five months before labelling a 0.5-0.6 m
77 deep trench was dug around each tree, then the trench was lined with a polyethylene
78 film and backfilled. All roots and root exudates inside this perimeter therefore
79 originated from the isolated tree, and were contained in this trench volume. The area
80 delimited by the trench was about 5 m². The distance between each tree was at least
81 20 m.

82

83 **2.2. ¹⁵N pulse-labelling**

84 Three labelling campaigns were carried out: the first (L₁) on the foliage at the end of
85 May (2009/05/27); the second (L₂) on the soil at the beginning of September
86 (2009/09/09); and the third (L₃) on the soil the following March (2010/03/20). All
87 labelling campaigns were conducted on sunny days. Two oaks were labelled during
88 each campaign: trees 1 and 2 during L₁; trees 3 and 4 during L₂; and trees 5 and 6
89 during L₃. 50% of buds showing leaf unfolding (Vitasse et al., 2009), occurred in
90 those sessile oaks on April 20, 2010; this date was defined as budburst. The L₁
91 campaign consisted of homogenous spraying on all foliage of 5g ¹⁵NH₄¹⁵NO₃ (98
92 atom %), i.e. 1.82g of ¹⁵N, dissolved in 2.5 L distilled water. Prior to L₁, soil of the
93 surrounding trenches was protected with a plastic tarpaulin covering the whole area
94 of the trenched plot, to avoid soil pollution with ¹⁵N. The tarpaulin was sealed to the
95 trunk at 50 cm height with Terostat-VII (Teroson, Henkel, Germany). It remained on
96 the soil during 2 weeks after labelling. Before removing the plastic tarpaulin, crowns

97 were sprayed with distilled water in order to avoid any soil contamination after the
98 removing of the tarpaulin.

99 This first campaign aimed at the labelling of foliage and, subsequently, of the N
100 reserves developed from remobilization of leaf N the following autumn. The L₂
101 campaign consisted of homogenous spraying of 5g ¹⁵NH₄¹⁵NO₃ (98 atom %), i.e.
102 1.82g of ¹⁵N, dissolved in 20 L distilled water on the soil of the trench plot of two
103 other selected oak trees (3 and 4). With this procedure, N reserves developed from
104 autumnal soil N uptake were expected to be labelled. The third and last labelling
105 campaign, L₃, consisted of homogenous spraying of 5g ¹⁵NH₄¹⁵NO₃ (98 atom %), i.e.
106 1.82g of ¹⁵N, dissolved in 20 L distilled water on the soil of the trench plot of trees 5
107 and 6, thus labelling their spring N uptake.

108

109 **2.3. Sampling and analytical methods**

110 Leaves, twigs, trunk phloem and xylem and soil monoliths (15 cm depth, very few
111 fine roots were present below 15 cm depth) of each labelled trees (1, 2, 3, 4, 5, 6)
112 were sampled after labelling until the end of 2010 (Table 1). At each sampling date
113 20 leaves and 20 twigs were collected randomly throughout the crown. Sampling was
114 always performed between 10:00 and 12:00 h UTC. The leaves were rinsed with
115 distilled water to remove any excess ¹⁵N. At each sampling date, two small disks of
116 bark (14 mm diameter, 10 mm depth) were collected at 1.3 m height using a corer.
117 Thereafter, phloem and xylem tissues were separated by hand with a cutter blade.
118 The leaf mass per area (LMA) was measured at each sampling date. Fine roots were
119 hand-picked from the soil monoliths, and washed with a 0.5 M CaCl₂ isotonic
120 solution. Soil adhering to roots was removed with a brush and sieved at 2 mm. All
121 plant tissues and soil samples were brought to the laboratory in a cooler. Plant tissues

122 were lyophilized and ground to a fine powder with a ball mill before analyses. At
123 each sampling date, one aliquot of each plant powder (1 mg) was transferred into tin
124 capsules (Elemental Microanalysis, UK, 6 x 4 mm, ref. D1006, BN/139877). At
125 some dates (Day After Labelling (DAL) 1, 126, 337, 460 for leaves and twigs of L₁;
126 DAL 126, 337, 460 for roots of L₁; DAL 227 and 350 for leaves and twigs of L₂;
127 DAL 49 and 350 for roots of L₂ and DAL 40 and 166 for leaves, twigs and roots of
128 L₃), four aliquots of powder was transferred into tin caps in order to test the
129 repeatability of the analysis. Total N concentration of plant and soil samples, was
130 analysed by dry combustion using an N auto-analyser (Flash EA 1112 series,
131 Thermofinnigan). ¹⁵N abundance was quantified in the same plant and soil fine
132 powder aliquots with a mass spectrometer (PDZ Europa, University of Davis,
133 Isotopes Facility, California).

134 Microbial N contents of fresh soil samples were determined using the chloroform
135 fumigation–extraction method (Vance et al., 1987). 2 fresh soil subsamples of 10 g
136 were prepared. One subsample was fumigated for 24 h with chloroform vapour,
137 while the other was not fumigated. Nitrogen extraction was performed using 50 mL
138 of 0.5 M K₂SO₄ for 30 min under vigorous shaking. The extracts (fumigated and not
139 fumigated) were filtered, then analysed for N content using an N analyser (TNM-1,
140 Shimadzu, Champs-sur-Marne, France). The microbial ¹⁵N abundance was estimated
141 using the same procedure except that the extraction solution was 0.03 M of K₂SO₄ in
142 order to avoid any alteration of the mass spectrometer with the K₂SO₄ salt during ¹⁵N
143 analysis.

144

145 **2.4. Calculations**

146 All ^{15}N enrichments were corrected for the background natural abundance of this
 147 isotope, using control values determined in plants and soils just before labelling. The
 148 seasonal variations of the natural ^{15}N abundance of each compartments were also
 149 followed all long the season, those variations were very weak, consequently, it has
 150 been choose to use the ^{15}N natural abundance of the labelled trees just before
 151 labelling. The total weight of each compartment analysed (i.e. leaves, twigs, trunk
 152 phloem and xylem, and fine roots) was extrapolated from that of six equivalent trees
 153 (same size and same diameter) grown on the same site under the same conditions.
 154 Those trees were felled as follows: two in October of the first labelling year (2009);
 155 two in the following May (2010); and two the following February (2011). Total leaf
 156 biomass was corrected according to the LMA. All data were expressed as proportion
 157 of recovered ^{15}N (PRN) in a specific compartment using the following
 158 calculation Eq. (1):

$$\text{PRN \%} = \frac{Q^{15}\text{N}_{\text{compartment}}}{\text{Max } Q^{15}\text{N}} \times 100$$

159 where $Q^{15}\text{N}$ was the quantity of ^{15}N recovered from a compartment on a specific
 160 date, and $\text{Max } Q^{15}\text{N}$ was the maximum quantity of ^{15}N recovered from all the
 161 sampled compartments during the experiment.
 162

163 The % contribution of each ^{15}N source (L_1 : leaves; L_2 : autumn soil N; L_3 : spring
 164 soil N) to the ^{15}N recovered in the roots in autumn or in the leaves of the second year
 165 as determined according to the following calculation Eq. (2) :

$$\% \text{ contribution } ^{15}\text{N}_{L_1, L_2, L_3} = \frac{(Q^{15}\text{N}_{\text{compartment}} / \text{Max } Q^{15}\text{N})_{L_1, L_2, L_3}}{\Sigma(Q^{15}\text{N}_{\text{compartment}} / \text{Max } Q^{15}\text{N})_{L_1, L_2, L_3}} \times 100$$

166
 167

168 **3. Results**

169 For each labelling, the two trees analysed displayed similar patterns of total
170 recovered ^{15}N in each compartment (data not shown) and ^{15}N partitioning throughout
171 the experiment. Moreover, the test of repeatability of the analysis revealed very few
172 variability of the ^{15}N partitioning at a specific date in a specific compartment (Fig.
173 1, 2, 3). Consequently, results was expressed as the mean of both trees (L_1 : 1+2; L_2 :
174 3+4, L_3 : 5+6).

175

176 **3.1. ^{15}N partitioning within the plant-soil system during the first leafy season**

177 ***3.1.1. After the foliar labelling in spring (L_1 , May 27, 2009)***

178 The total balance for the administered ^{15}N demonstrated maximum recoveries of ^{15}N
179 within the plant-soil system of 32% one day after leaf labelling. It decreased to
180 13.5% of the administered ^{15}N recovered in the sampled compartments at the end of
181 September (126 days after labelling) (Table 1).

182 The PRN was maximum in leaves (96%, Fig. 1a) one day after L_1 , then decreased
183 continuously during the four following months (from May 27 to September 30, 2009,
184 i.e. until the 126th day after labelling) with a mean decrease of 80% between these
185 two dates (Fig. 1a). The same pattern was observed in twigs, where the PRN
186 decreased from 3% on day 1 to 0.4% on day 126 (Fig. 1a).

187 In the trunk phloem tissue and the fine roots, the PRN stayed relatively stable or
188 slightly increased until day 57 (July 24, 2009). They then increased until day 126
189 (September 30, 2009), when they reached 4.75% in the phloem and 16% in the roots
190 (Fig. 1b, c). The PRN from the rhizospheric soil and microbial biomass was less than
191 1% (Fig. 1d). During winter (December 2, 2009; day 189) the PRN reached 18.5% in
192 fine roots (Fig.1c).

193 ***3.1.2. After the first soil labelling (L_2 , September 9, 2009)***

194 The total balance for the administered ^{15}N demonstrated maximum recoveries within
195 the plant-soil systems three days after L_2 of 70%. By the end of October (49 days
196 after labelling), recoveries from the sampled compartments decreased to 22% of the
197 administered ^{15}N (Table 1).

198 Three days after labelling, 3% of the recovered ^{15}N was present from the fine roots
199 (Fig. 2c). Nine days after labelling (September 18, 2009), the PRN showed that the
200 majority of the ^{15}N was recovered from the soil, with 61% of the ^{15}N recovered from
201 the rhizospheric soil and 32.5% from the microbial biomass (Fig. 2d). During the
202 following 40 days (until October 28, 2009), the PRN from the soil decreased to 8.5%
203 in the rhizospheric soil and 9.5% in the microbial biomass (Fig. 2d). On the same
204 date, 6% of the ^{15}N was recovered from the fine roots (Fig. 2c). Less than 1% of the
205 ^{15}N was recovered from the phloem, xylem and twigs (Fig. 2a, b). In December (day
206 84) the PRN from the soil was similar to that of the previous date and 4% of the ^{15}N
207 was recovered from the fine roots (Fig. 2c, d).

208

209 **3.2. ^{15}N partitioning within plant-soil system before and after budburst**

210 Almost one year after the first labelling (L_1), and before budburst (April 8, 2010, 318
211 days after labelling), 7.5% of the ^{15}N were recovered in the sampled compartments.
212 Thereafter, recovery remained stable at around 12% until September (460 days after
213 labelling, Table 1).

214 On April 8, 2010, i.e. 318 days after L_1 , 11.5% of the recovered ^{15}N was found in
215 fine roots (Fig. 1 c). Twigs contained 4.5% of recovered ^{15}N (Fig. 1a), while phloem
216 contained 4% (Fig. 1b). Less than 0.5% of ^{15}N was recovered from the rhizospheric
217 soil and microbial biomass (Fig. 1d).

218 Eight days after budburst (April 28, i.e. 337 days after L₁), 25% of the recovered ¹⁵N
219 was observed in new leaves. By May 19, this had decreased to 17% (Fig. 1a). On
220 April 28, twigs contained 3.5% of the recovered ¹⁵N (Fig. 1 a), phloem 4% (Fig. 1b)
221 and fine roots 10% (Fig. 1c). From then until September (i.e. 460 days after
222 labelling), the PRN from leaves remained relatively stable (22%), whereas it largely
223 decreased in fine roots (0.35%) (Fig. 1a, b, c). Less than 0.2% of the total ¹⁵N
224 recovered over the season was from the rhizospheric soil and microbial biomass (Fig.
225 1d).

226 Just before budburst following the second labelling (L₂, April 8, 2010, 208 days after
227 labelling) 19% of the ¹⁵N administered were recovered from all the analysed
228 compartments (Table 1). Most of it was from the rhizospheric soil (14.5%, Fig. 2d).
229 The microbial biomass contained 9.5% of the recovered ¹⁵N and the fine roots 2%
230 (Fig. 2d, c). The rest of the ¹⁵N (less than 5%) was distributed between the twigs,
231 trunk phloem and xylem (Fig. 2a, b). The same pattern was observed eight days after
232 budburst (227 days after labelling): most of ¹⁵N was recovered from soil microbial
233 biomass and rhizospheric soil (12%, Fig. 2d); 2.25% was recovered from fine roots;
234 3.5% of ¹⁵N was recovered from phloem and xylem; only 0.5% was recovered from
235 new leaves (Fig. 2a).

236 From April 8 (208 days after labelling) to May 19 (247 days after labelling, and 30
237 days after budburst), the PRN decreased in soil microbial biomass and rhizospheric
238 soil (7%), but increased in fine roots (9.5%) (Fig. 2 d, c). A noticeable increase of the
239 PRN from leaves was also observed at this date (4.5%, Fig. 2a). Thereafter, the PRN
240 from soil microbial biomass and fine roots decreased slightly from May 19 to June
241 28 (i.e. 247 to 287 days after labelling), then remained stable until the end of August
242 (Fig. 2d, c). The PRN from leaves increased to 7% in June (Fig. 2a).

243 For trees whose soils were labelled in spring (L₃, March 20, 2010), the maximum
244 recovery of the administered ¹⁵N occurred 40 days later: 51.5% from the sampled
245 compartments. Recovery decreased thereafter and stabilized at 19.5% until autumn
246 2010 (Table 1).

247 Twenty days after labelling and before budburst, the soil microbial biomass
248 contained 44.5% of the recovered ¹⁵N and the rhizospheric soil 39% (Fig. 3d). The
249 remaining ¹⁵N was mainly located in the roots (2% of recovered ¹⁵N, Fig. 3c). 8 days
250 after budburst, the PRN was quite similar: 61% in microbial biomass and 32% in
251 rhizospheric soil (Fig. 3d). ¹⁵N recovered from fine roots followed a pattern similar
252 to that observed on the previous sampling occasion (Fig. 3c). However, between 8
253 and 30 days after budburst (from April 28 to May 19, 2010 i.e. from 40 to 61 days
254 after labelling), the PRN in microbial biomass and in rhizospheric soil decreased
255 sharply to 3.2% (Fig. 3d). On that date, 17% of the ¹⁵N was recovered from the fine
256 roots (Fig. 3c) and 21.2% from the leaves (Fig. 3a). The PRN from leaves remained
257 stable until the beginning of June (74 days after labelling) (Fig. 3a). From that date
258 until September the PRN from leaves and fine roots declined slightly (Fig. 3a, c).
259 The PRN from microbial biomass decreased continuously throughout the season and
260 reached 2.5% in September (day 166 after labelling) (Fig. 3d).

261

262 **4. Discussion**

263 **4.1. Efficiency of labelling**

264 Isotope labelling experiments are technically challenging, and as a consequence are
265 very scarce on trees growing in natural conditions. In this paper, field labelling
266 campaigns were conducted on 20-year-old naturally regenerated oaks. For each
267 campaign (only) two trees were labelled. Nevertheless the similarity of the results

268 between them suggests that the observed ^{15}N partitioning in soil and tree is a
269 representative view of the functioning of such systems

270 During the first labelling procedure (L_1), a significant fraction of the added
271 $^{15}\text{NH}_4^{15}\text{NO}_3$ was incorporated into the leaves of the sessile oaks. A significant
272 proportion of the ^{15}N was allocated to the leaves: more than 90% of the ^{15}N was
273 recovered from this compartment. The total balance for the administered ^{15}N
274 demonstrated maximum recoveries within the plant-soil systems of 32% one day
275 after leaf labelling. The remaining ^{15}N was probably lost by leaf leaching. However,
276 soil protection with plastic tarpaulins avoided all contamination of soil and roots as
277 indicated by the ^{15}N recovered in the belowground compartments (Fig. 1d).
278 Thereafter, the recovery of administered ^{15}N from the sampled compartments
279 decreased to 14.5%, probably due to allocation of ^{15}N to non-harvested
280 compartments, such as old branches, coarse roots or the inner part of the trunk.
281 Indeed, data currently available on woody plants show that nitrogen is re-
282 translocated from leaves to storage sites such as old branches, trunk or coarse roots
283 (Valenzuela Nunez et al., 2011; Bazot et al., 2013). The soil $^{15}\text{NH}_4^{15}\text{NO}_3$ labelling
284 (L_2) conducted in September was also effective. Indeed, the total balance for the ^{15}N
285 applied to the soil demonstrated maximum recoveries within the plant-soil systems of
286 70%; 3 days after soil labelling. The rest of the ^{15}N was most probably lost by soil
287 leaching (30% of the ^{15}N provide). Thereafter the recovery of administered ^{15}N from
288 the harvested compartments decreased to 22%. As with the leaf-labelling experiment
289 (L_1), this decrease was presumably due to allocation of ^{15}N to non-harvested
290 compartments. Finally, the soil $^{15}\text{NH}_4^{15}\text{NO}_3$ labelling carried out the following March
291 (L_3) was also effective, with maximum recoveries within the plant-soil systems of

292 51.5%, 40 days after soil ^{15}N labelling. This recovery decreased to a mean of 19%
293 during the rest of the season.

294

295 **4.2. N dynamics in soil-tree systems during the first leafy season**

296 Following the first labelling procedure, the ^{15}N was quickly incorporated into leaves;
297 more than 90% of the ^{15}N applied was accounted for in leaves one day after
298 labelling. Thereafter this portion decreased continuously along the season. The
299 unaccounted for fraction of the ^{15}N had presumably been transferred to other
300 compartments, including those which were not sampled, i.e. branches and coarse
301 roots.

302 This important foliar N remobilisation was observed to continue in leaf-labelled trees
303 until yellowing, i.e. the end of September. Data currently available on woody plants
304 show that nitrogen is mainly re-translocated from leaves to storage sites during the
305 autumn (Coleman and Chen, 1993;Cooke and Weih, 2005;Dong et al., 2002;Taylor,
306 1967), due to the predominant role of leaf senescence in the constitution of N stores.
307 Leaf senescence leads to the breakdown of leaf proteins, the transfer of their nitrogen
308 to the perennial plant parts and the formation of N storage compounds (vegetative
309 storage proteins and amino acids) (Dong et al., 2000;Tromp, 1983). In this study, a
310 noticeable increase of percentage of recovered ^{15}N in fine roots was observed on
311 September 30 (16%). This compartment could be defined as a storage compartment
312 in young sessile oaks. Such an observation has been already reported for oaks of the
313 same pole stand (Gilson et al., 2014), and similar findings were reported for field-
314 grown adult peach trees by Tagliavini et al (1997), being typical of other young
315 deciduous trees (Millard and Proe, 1991;Salaün et al., 2005;Tromp and Ovaas,
316 1979;Wendler and Millard, 1996). On this date (end of September), branches and

317 coarse roots could also have contributed significantly to N storage, as previously
318 described (Bazot et al., 2013).

319 At the same time, root uptake can also contribute directly to storage, as proposed by
320 Millard (1996). Indeed, 49 days after labelled ^{15}N had been applied to surrounding
321 soil (L_2), in September, 5.75% was recovered from the trees' fine roots. It can be
322 underlined that at the end of September, foliage ^{15}N made up 73% of the ^{15}N
323 recovered in roots, whereas soil ^{15}N uptake contributed to 27% of the ^{15}N recovered
324 in roots (eq. 2, Fig. 4). The soil N uptake in this period was mainly recovered in the
325 root system; there was little labelled N in the rest of the trees. This is consistent with
326 the results of Tagliavini et al (1997) and Jordan et al (2012), who found a significant
327 fraction of labelled N in fine root samples of peach trees supplied with ^{15}N applied
328 on soil before fruit harvest in September.

329 Concomitantly with root N uptake for storage, notably in fine roots, a strong
330 immobilization of N in microbial biomass was observed. Indeed, on October 7 (i.e.
331 28 days after labelling), when yellowing was well advanced, 12.5% of the applied
332 ^{15}N was recovered in microbial biomass and 21.5% in rhizospheric soil: there was a
333 competition for soil N between microbial N immobilization and reserve synthesis by
334 root N uptake at that time. This is consistent with the idea that soil microorganisms
335 are strong short term-competitors for soil N due to their high surface area to volume
336 ratio, wide spatial distribution in the soil and rapid growth rates, compared with
337 plants roots (Hodge et al., 2000). Thereafter, root N uptake was still efficient during
338 late yellowing (between October 7 and October 28), since ^{15}N recovered from the
339 fine roots slightly increased from 3.5% to 5.5%, whereas that recovered from
340 microbial biomass decreased from 12.5% to 10%. This could be explained by
341 microbial mortality and turnover, which releases N to the soil, combined with the

342 capacity of plants to sequester N for longer (Barnard et al., 2006;Bloor et al.,
343 2009;Hodge et al., 2000).

344 After leaf fall, trees may have a significant capacity for nitrate uptake in the fine
345 roots in midwinter (i.e. in the absence of leaves), as already shown in Japan oak
346 (Ueda et al., 2010). However, in our case, N soil uptake was limited by low soil
347 temperature, which affected the mineralization rate and root activity, since the ^{15}N
348 recovered from roots slightly decrease between October 28 and December 2 (5.5% to
349 4%) and then declined to 1.75% between December 2 and April 8.

350

351 **4.3. N dynamic in soil tree system the following spring**

352 In April (before budburst), for trees with leaves labelled in the previous year (L_1), the
353 most part of ^{15}N was recovered in their roots (11.5%). On the other hand, at the same
354 date, most of the labelled N applied to soil in September (L_2) was recovered from the
355 rhizospheric soil (14.5%). When soil (and hence spring N uptake) was labelled (L_3)
356 at the beginning of March, a month later most of the ^{15}N was recovered from
357 microbial biomass and rhizospheric soil (81%), but a small proportion of ^{15}N was
358 recovered from the fine roots (1.5%). The latter demonstrated a small N uptake
359 before budburst, as has previously been observed in Japan oak (Ueda et al., 2010).
360 This early N uptake from the soil could be related to sessile oak's hydraulic
361 properties. As a ring-porous species, sessile oak achieves 30% of its annual radial
362 stem growth before leaf expansion in spring (Breda and Granier, 1996). Water flow
363 pathways are then restored each spring before the onset of transpiration (Breda and
364 Granier, 1996). This enables early root N uptake from soil as soon as a threshold soil
365 temperature is reached.

366 Eight days after budburst, most of the ^{15}N applied to leaves (L_1) was recovered from
367 new leaves (25.2%) and new twigs (mean of 3.5%). This clearly underlined that a
368 significant proportion of ^{15}N used to synthesize new leaves came from ^{15}N stored
369 during the previous autumn, as shown for *Ligustrum* (Salaün et al., 2005). Moreover,
370 this N came from foliar N of the previous year, not from soil N uptake during the
371 previous autumn. Indeed, trees labelled the previous autumn on soil (L_2) showed a
372 similar partitioning of ^{15}N in leaves and twigs before budburst (208 days after
373 labelling) and eight days after budburst (227 days after labelling), there was no
374 mobilisation of ^{15}N for the new leaves and twigs synthesis for those trees. Less than
375 1% of ^{15}N taken up from soil before budburst was recovered in leaves and twigs
376 eight days after budburst. A distinction might be made between stored N sourced
377 from leaves and that sourced from soil, stored mainly in roots. N from leaves could
378 be stored as amino acids in branches, trunk, and coarse roots, whereas N taken up
379 from soil could be stored in roots as NO_3^- . This N was not converted into amino acids
380 by Glutamine synthetase / Glutamate synthase enzymes during winter, most probably
381 due to low enzymatic activity in roots during winter (Bazot et al., 2013). As a
382 consequence, the following spring, trees first remobilized easily circulating forms of
383 N, and N stored nearer to demands. Indeed in trees, NO_3^- is hardly transported to
384 their leaves but rather turned into amino acids in their roots (Morot-Gaudry, 1997).
385 Indeed roots were the main site of NO_3^- reduction (Gojon et al., 1991). Consequently,
386 soil ^{15}N was not the main contributor to the synthesis of new twigs and new leaves
387 during the eight first days after budburst. At this time, 95% of new leaves ^{15}N came
388 from ^{15}N -labelled reserves, 2% from soil labelled the previous autumn, and only 3%
389 from soil labelled in the current spring (Eq. 2, Fig. 4). Previous studies have also
390 found that N reserves contribute significantly to leaf expansion in young trees: in

391 white birch (Wendler and Millard, 1996); sycamore maple (Millard and Proe, 1991);
392 Japan oak (Ueda et al., 2009); pedunculate oak (Vizoso et al., 2008); and sessile oak
393 (El Zein et al., 2011a).

394 Considering trees whose soil had been labelled in autumn (L_2), eight days after
395 budburst the proportion of recovered ^{15}N in microbial biomass decreased slightly
396 whereas it slightly increased in fine roots compared to the previous sampling date.
397 One can suppose that the increased soil temperature and the first flux of C from plant
398 to soil (rhizodeposition) stimulated microbial biomass turnover, making ^{15}N
399 available for root uptake. Very little ^{15}N was recovered from the other compartments
400 of the trees.

401 Soil N uptake became really effective between 8 and 30 days after budburst. Indeed,
402 whatever the date of the soil labelling (autumn or the current spring), 30 days after
403 budburst, a sharp decrease in ^{15}N in the microbial biomass was observed, depending
404 on an increase of ^{15}N in fine roots and in young leaves. In June 28 (at leaf maturity),
405 40% of the ^{15}N recovered from leaves came from stored ^{15}N , 10% came from ^{15}N
406 applied to soil the previous autumn, and 40% came from ^{15}N applied on soil the
407 current March, one month before budburst (Eq. 2, Fig. 4). This pattern of
408 contribution was maintained throughout the season. Similar findings have been
409 reported for other species. For example, 20-30% of shoot leaf N was supplied by
410 spring-applied fertilizer for mature pear trees (Sanchez et al., 1990) and mature
411 almond trees (Weinbaum SA, 1984), while only 13% of a solution of nitrate-N and
412 ammonium-N applied to soil, contributed to total leaf N of apple trees (Nielsen et al.,
413 1997). *Sorbus aucuparia* had remobilized half the N from storage before any was
414 taken up by the roots (Millard et al., 2001). Finally, there is a concomitant/concurrent

415 remobilization and uptake of N from the soil by some other species, as shown for
416 scots pine (Millard et al., 2001) and walnut (Frak et al., 2002).

417

418 **5. Conclusion**

419 This paper completes knowledge of internal and external nitrogen cycles in a forest
420 ecosystem. We highlighted that in autumn, N reserves are formed from N
421 remobilized from leaves and N uptake by roots. This N is stored in roots, principally
422 most probably in the form of amino-acids and nitrate. Those reserves, especially N
423 coming from leaves, contributed significantly to new tissue synthesis the following
424 spring. Nevertheless, N uptake was also observed in spring before budburst; this N
425 was not transferred to new twigs and new leaves during the first days following
426 budburst. N uptake from soil only contributed significantly to the synthesis of new
427 tissues when leaves were fully expanded. Two months after budburst the relative
428 contributions of ^{15}N originating from leaves and ^{15}N uptake from soil were 40:60,
429 whereas they were 95:5 eight days after budburst.

430

431 **Acknowledgements**

432 Financial support was provided by Ecology Systematic Evolution lab and the French
433 National Research Agency through the “CATS Carbon Allocation in Tree and Soil
434 project”. The authors would like to acknowledge the contributions of Jérôme Ngao
435 and Daniel Berveiller to data collection and field work, and Michèle Viel and
436 Patricia Le Thuaut for technical assistance. We are grateful to the French National
437 Forest Office (ONF) for allowing us to carry out these experiments.

438

439 **Author contribution statement**

440 SB and LB conceived and designed the experiments. SB, CF and LB conducted all
441 field and laboratory analyses. SB carried out data analysis, wrote most of the
442 manuscript and prepared the figures. CF, CD and LB contributed to the writing of the
443 manuscript.

594 **Table**

595 Table 1 :

596 Labelling characteristics and recovery of ^{15}N administered in each labelling

597 campaign from the sampled compartments of each tree, on each sampling occasion

598 (DAL : Days after Labelling, JD :Julian day number).

Tree	1	2	3	4	5	6			
Labelling date	2009/05/27	2009/05/27	2009/09/09	2009/09/09	2010/03/20	2010/03/20			
	DAL/JD	% of recovered ^{15}N		DAL/JD	% of recovered ^{15}N		DAL/JD	% of recovered ^{15}N	
Year 1	1/148	39	25	3/255	68	72			
	3/150	31	25	6/258	68	50			
	6/153	30	24	9/261	68	70			
	9/156	22	19	16/268	33	38			
	16/163	19	16	28/280	31	22			
	30/177	17	15	49/301	29	15			
	57/205	17	14	84/336	29	14			
	126/273	15	14						
Year 2	189/336	14	13						
	318/98	8	7	208/98	24	14	20/98	65	28
	337/118	11	13	227/118	12	10	40/118	63	40
	358/139	10	13	247/139	16	20	61/139	16	14
	370/152	14	14	260/152	22	21	74/152	20	25
	397/180	11	10	287/180	38	18	102/180	20	25
	460/244	13	11	350/244	13	12	166/244	18	21
	509/293	7	5	399/293	10	8	215/293	11	21

600

601 **Figure captions**

602 Figure 1 : Partitioning of recovered ^{15}N (PRN%) from the sampled compartments
603 following the first labelling campaign, i.e. from May 26, 2009 to October 20, 2010.
604 a. leaves \blacklozenge and twigs \times , b. phloem Δ , c. fine roots \circ , d. rhizospheric soil \blacksquare and
605 microbial biomass $+$ (for those compartments the Y axis was adjusted to 1). DAL:
606 Days after labelling. The two lines, continuous and dotted, correspond to tree 1 and
607 tree 2. Vertical bars indicate standard errors.

608

609 Figure 2 : Partitioning of recovered ^{15}N (PRN%) from the sampled compartments
610 following the second labelling campaign, i.e. from September 08, 2009 to October
611 20, 2010; a. leaves \blacklozenge and twigs \times , b. phloem Δ , c. fine roots \circ , d. rhizospheric soil \blacksquare
612 and microbial biomass $+$. DAL: Days after labelling. The two lines for each category
613 (continuous and dotted) correspond to tree 3 and tree 4. Vertical bars indicate
614 standard errors.

615

616 Figure 3 : Partitioning of recovered ^{15}N (PRN%) from the sampled compartments
617 following the third labelling campaign, i.e. from April 8, 2010 to October 20, 2010;
618 a. leaves \blacklozenge and twigs \times , b. phloem Δ , c. fine roots \circ , d. rhizospheric soil \blacksquare and
619 microbial biomass $+$. DAL: Days after labelling. The two lines for each category
620 (continuous and dotted) correspond to tree 5 and tree 6. Vertical bars indicate
621 standard errors.

622

623 Figure 4 : Conceptual scheme representing percentage contributions of ^{15}N (Eq. 2)
624 from each labelling campaign (L_1 : white, L_2 : light grey, L_3 : dark grey) in roots in the
625 autumn, and in new leaves in the season following the first labelling campaign.
