## 21 **Abstract**

22 In order to fully constrain paleo-carbonate systems, proxies for two out of seven  
23 parameters, plus temperature and salinity are required. The boron isotopic  
24 composition ( $\delta^{11}\text{B}$ ) of planktonic foraminifera shells is a powerful tool to reconstruct  
25 changes in past surface ocean pH. As  $\text{B}(\text{OH})_4^-$  is substituted into the biogenic calcite  
26 lattice in place of  $\text{CO}_3^{2-}$ , it has been suggested that B/Ca ratios in biogenic calcite are  
27 a possible proxy for  $[\text{CO}_3^{2-}]$ . However, differentiating between the effects of pH and  
28  $[\text{CO}_3^{2-}]$  is problematic, as they co-vary closely in natural systems, and so the major  
29 control on boron incorporation remains unclear. To deconvolve the effects of pH and  
30  $[\text{CO}_3^{2-}]$  on the B/Ca ratio and to test whether  $\delta^{11}\text{B}$  remains constant at constant pH,  
31 but under changing  $[\text{CO}_3^{2-}]$  (pH 8.05 with 238, 285 and 532  $\mu\text{mol kg}^{-1} \text{CO}_3^{2-}$ ) and  
32 vice versa, we decoupled pH and  $[\text{CO}_3^{2-}]$  ( $276 \pm 19.5 \mu\text{mol kg}^{-1} \text{CO}_3^{2-}$  with pH 7.7,

33 7.9 and 8.05) and grew the planktonic foraminifer *Orbulina universa* in these  
34 manipulated culture media. Measurements of the isotope composition of boron and  
35 the B/Ca ratio were performed simultaneously using a femtosecond laser ablation  
36 system coupled to an MC ICP-MS. Results show that  $\delta^{11}\text{B}$  is controlled by pH and  
37 does not respond to changes in  $[\text{CO}_3^{2-}]$ . On the other hand, the B/Ca ratio is driven by  
38  $[\text{HCO}_3^-]$  independently of pH. This suggests that B/Ca ratios in foraminiferal calcite  
39 may be used as a second, independent, proxy for paleo-carbonate system  
40 reconstructions.

42

43

#### 44 **Introduction**

45

46 Before the Anthropocene, the atmospheric  $\text{CO}_2$  concentration was governed by the  
47 surface ocean  $[\text{CO}_2]$ , simply because the carbon content of the ocean is 65 times  
48 larger than that of the atmosphere (Siegenthaler and Sarmiento, 1993). Hence,  
49 understanding the global carbon cycle and the evolution of atmospheric  $p\text{CO}_2$  in Earth  
50 history requires knowledge of the dynamics of the oceanic carbonate chemistry. The  
51 unprecedented magnitude and rate of carbon emissions since the industrial revolution  
52 has resulted in warming, and acidification of the ocean (Bijma et al., 2013; Ciais et  
53 al., 2013; Gattuso and Hansson, 2011; Rhein et al., 2013). As a result, the interest in  
54 the reconstruction of seawater carbonate chemistry to identify ocean acidification in  
55 Earth history experienced another impetus (Hönisch et al., 2012; Martínez-Botí et al.,  
56 2015). The reconstruction of the full oceanic carbonate chemistry requires proxies of  
57 at least two independent parameters of the carbonate system, in addition to  
58 temperature and salinity.

59

60 The most promising tool, for reconstructing pH is the boron isotopic composition  
61 ( $\delta^{11}\text{B}$ ) of biogenic carbonate producers such as foraminifera and corals (Hönisch et  
62 al., 2004; Rae et al., 2011; Sanyal et al., 2001; Sanyal et al., 1996). Boron exists in  
63 seawater primarily in the form of two species, boric acid ( $\text{B}(\text{OH})_3$ ) and borate ion  
64 ( $\text{B}(\text{OH})_4^-$ ; Fig. 1A). As for all weak acids, the relative abundance between these two  
65 species is controlled by pH (Dickson, 1990; DOE, 1994). Because of the isotopic  
66 fractionation between the two aqueous species (Fig 1B;  $\alpha_{4-3} = R_{\text{B}(\text{OH})_4^-}/R_{\text{B}(\text{OH})_3}$ ), the  
67 boron isotopic composition of each species is also pH dependent (Hemming and

68 Hanson, 1992; Palmer et al., 1987; Sanyal et al., 1996; Sanyal et al., 2000). At low  
69 pH (<7) nearly all boron is present in the form of boric acid, whereas at high pH (>10)  
70 boron primarily exists as borate.  $B(OH)_3$  is enriched in the stable isotope  $^{11}B$   
71 compared to  $B(OH)_4^-$ , with a constant isotopic fractionation of 27.2 ‰ between the  
72 two boron species (Klochko et al., 2009; Klochko et al., 2006). Consequently, as the  
73 relative concentration of the dissolved species changes with pH, so does their isotopic  
74 composition. Because it is assumed that only the charged species, borate, is  
75 incorporated into the calcite lattice (Hemming and Hanson, 1992; Vengosh et al.,  
76 1991) the boron isotopic composition of marine carbonates thus records the pH that  
77 prevailed when the calcium carbonate was precipitated.

78

79 The  $\delta^{11}B$  of marine calcifiers such as corals, bivalves, foraminifera, pteropods, etc.  
80 can be used as a proxy for paleo pH and therefore provide clues on the evolution of a  
81 key parameter of the oceanic carbonate chemistry. For instance, Spivack et al. (1993)  
82 estimated that the pH of the surface ocean may have changed from 7.4 in the Miocene  
83 to 8.2 in the Holocene. Sanyal et al. (1995) estimated that during the last glacial  
84 maximum the deep ocean pH was about 0.3 pH unit higher and the surface ocean pH  
85 about 0.2 pH unit higher compared to that of the modern values. Inspired by such  
86 promising results several groups took on the challenge to reconstruct ocean pH. In the  
87 subsequent years, many studies have dealt with reconstructing past oceanic pH across  
88 different time scales using the boron isotopic composition of mainly foraminifera but  
89 also corals (Foster et al., 2012; Foster et al., 2006; Hemming et al., 1998; Hönisch et  
90 al., 2011; Hönisch et al., 2008; Hönisch and Hemming, 2005; Hönisch et al., 2009;  
91 Hönisch et al., 2007; Hönisch et al., 2012; Martínez-Botí et al., 2015; Palmer et al.,  
92 1998; Pearson and Palmer, 2000; Pearson and Palmer, 1999; Sanyal et al., 1997;  
93 Sanyal et al., 1995; Spivack et al., 1993).

94

95  $\delta^{11}B$  is proved to be a reliable recorder of pH but, in the aforementioned  
96 reconstructions, the second carbonate system parameter used to reconstruct  $pCO_2$  was  
97 based on assumptions. In existing boron-based reconstructions, investigators  
98 attempted to estimate total alkalinity ( $A_T$ ) or  $[CO_3^{2-}]$  from modern ocean conditions or  
99 reconstructions of carbonate compensation depth (CCD). In the modern ocean  $A_T$  is  
100 linearly correlated with salinity, because total alkalinity is the charge balance between

101 the major conservative ions in seawater, and this charge balance varies with salinity  
102 (Dickson, 1981; Dickson, 1992; Wolf-Gladrow et al., 1999; Wolf-Gladrow et al.,  
103 2007). Therefore, total alkalinity is a conservative parameter. It is assumed that the  
104 modern salinity– $A_T$  relationship was constant over time so that  $A_T$  can be estimated  
105 from reconstructions of salinity using sea-level records (Foster, 2008; Hönisch et al.,  
106 2009). However, salinity and alkalinity may be decoupled in space and time through  
107 weathering and changes in the hydrological cycle and, reliable proxies for regional  
108 salinity reconstructions are not available to date. Another approach is based on the  
109 assumption that seawater  $[Ca^{2+}]$  has remained proportional to  $A_T$  over time so that  $A_T$   
110 can be adjusted in a way that the water column is exactly saturated with respect to  
111 calcite at the lysocline (~500 m above the CCD; Pearson and Palmer, 2000). In other  
112 studies,  $[CO_3^{2-}]$  was estimated through adjusting the surface ocean  $[CO_3^{2-}]$  to match  
113 the CCD. The CCD, however, is not uniform through space and time (Van Andel,  
114 1975), calling into question these approaches for estimating past  $A_T$ .

115

116 Considering the relatively large uncertainties afflicted with the constraints described  
117 above, it is of utmost importance to develop proxies for a carbonate system parameter  
118 in addition to pH. A potential one is the B/Ca ratio of planktonic foraminifera that has  
119 been used as a proxy for estimating past changes in  $[CO_3^{2-}]$  (Foster, 2008), given that  
120 the concentration of borate  $B(OH)_4^-$  increases with pH and pH co-varies with  $[CO_3^{2-}]$ .  
121 However, it is challenging, if not impossible, to identify the parameter controlling  
122 B/Ca based on samples that have grown in natural seawater because pH and carbonate  
123 chemistry parameters co-vary closely in natural systems. To disentangle their effects  
124 on a proxy it is necessary to deconvolve the carbonate chemistry.

125

126 A more recent study (Allen et al., 2012) has shown that the B/Ca ratio of planktonic  
127 foraminifera also decreases with increasing total inorganic carbon ( $C_T$ ) or  $[HCO_3^-]$  at  
128 constant pH (i.e.  $[B(OH)_4^-]$  was constant while  $[CO_3^{2-}]$  and  $[HCO_3^-]$  were increased),  
129 suggesting that borate and carbon species compete for the inclusion into the calcite  
130 lattice. However, in this study pH was not decoupled from  $[CO_3^{2-}]$ , leaving the  
131 question open whether the B/Ca ratio in planktonic foraminifera is influenced by the  
132 ratio between  $[B(OH)_4^-]$  and  $C_T$  or  $[HCO_3^-]$ . Kaczmarek et al. (2015b) decoupled the  
133 carbonate chemistry and showed that B/Ca in the benthic foraminifer *Amphistegina*

134 *lessonii* is influenced by the ratio between  $[B(OH)_4^-]$  and  $[HCO_3^-]$ , rather than by pH  
135 or  $[CO_3^{2-}]$ . Recently, Henehan et al. (2015) suggested that B/Ca in *Globigerinoides*  
136 *ruber* might be controlled by  $[PO_4]$ . We believe that this relationship results from a  
137 co-variation between ocean carbonate chemistry and nutrients because respiration of  
138 organic matter will release both carbon and nutrients. Here we conducted experiments  
139 with a planktonic foraminifer and decoupled pH and  $[CO_3^{2-}]$ , as performed by  
140 Kaczmarek et al. (2015b). We also show that combined measurements of  $\delta^{11}B_{\text{calcite}}$   
141 and B/Ca of the same species as conducted in our study might be used to fully  
142 constrain the carbonate chemistry in Earth history.

143

144

## 145 **Methods**

### 146 *Collection and culturing:*

147 Living specimens of *Orbulina universa* were collected daily using a 57 cm diameter  
148 WP2 plankton net (200  $\mu\text{m}$  mesh size), between July and September 2012 at Point B,  
149 Villefranche-sur-Mer, France (43.41°N, 7.19°E) and maintained until gametogenesis  
150 in laboratory cultures at the Laboratoire d’Oceanographie de Villefranche.  
151 Established procedures for maintaining planktonic foraminifera in laboratory culture  
152 were used (Bemis et al., 1998; Bijma et al., 1998; Spero and Lea, 1993). Briefly,  
153 specimens were identified, measured with a light microscope, and transferred to 0.2  
154  $\mu\text{m}$ -filtered seawater, whose carbonate chemistry was accurately determined and  
155 subsequently modified. Specimens were maintained individually in air-tight 100 ml  
156 acid-washed SCHOTT DURAN® bottles that were sealed without an air space and  
157 placed upside down into thermostated water baths maintained at a temperature of  
158 23°C ( $\pm 0.2^\circ\text{C}$ ). Light was provided by 4, 39 W fluorescent tubes (JBL Solar Ultra  
159 Marin Day), with reflectors, (at a distance of ca. 15 cm from the water surface), with a  
160 12:12 h L: D photoperiod. The average irradiance, measured with a LI-193 sensor  
161 (LiCOR) in the culture jars was about 290  $\mu\text{mol photons m}^{-2} \text{s}^{-1}$ .

162

163 The foraminifers were fed a one-day-old brine shrimp *Artemia nauplius* every second  
164 day until gametogenesis. The brine shrimps were hatched in modified seawater from  
165 the same batch as used for culturing the foraminifera. Just prior to feeding, hatched  
166 nauplii were transferred once again to fresh medium from the same batch. After

167 feeding culture jars were topped up with medium from the same batch to prevent the  
168 formation of a headspace. Empty shells were collected within 24 h after successful  
169 gametogenesis, rinsed in deionised water and archived in covered micro paleo-slides  
170 for later analysis. Approximately 35 tests were grown for each experimental  
171 treatment. Culture water samples were collected at the start and end of the  
172 experiments to verify the boron concentration, its isotopic composition and the  
173 carbonate system parameters.

174

#### 175 *Modified seawater chemistry*

176 The objective of these experiments was to decouple seawater pH and  $[\text{CO}_3^{2-}]$  and  
177 create treatments with a constant pH and varying carbonate ion concentration and  
178 treatments with a constant carbonate ion concentration but varying pH. To decouple  
179 the effects of  $\text{pH}_T$  and  $[\text{CO}_3^{2-}]$ , seawater carbonate chemistry was modified  
180 manipulating  $\text{pH}_T$ , using NaOH and HCl, and dissolved inorganic carbon ( $C_T$ ) by  
181 adding gravimetrically carbonate and bicarbonate or bubbling with  $\text{CO}_2$ . Calculations  
182 were made using `csys_vari.m` (Zeebe et al., 2001) with carbonic acid dissociation  
183 constants of (Mehrbach et al., 1973). Temperature ( $23^\circ\text{C}$ ) and salinity (38.0) were  
184 kept constant (Table 1).

185

186 To enable single shell analysis by LA-MC-ICP-MS, the boron concentration was  
187 increased to about 10 times the concentration of natural seawater by adding boric acid  
188 to the culture water (see Sanyal et al., 2001; Sanyal et al., 1996; Sanyal et al., 2000).  
189 The  $\text{pH}_T$  and  $C_T$  were then modified via titration with boron free NaOH (1N) and HCl  
190 (1N) to bring the experimental pH to desired levels of  $7.70 \pm 0.03$ ,  $7.90 \pm 0.02$  and  $8.$   
191  $05 \pm 0.05$ , respectively. Culture water samples collected at the start and at the end of  
192 each experiment showed that pH remained nearly constant throughout each  
193 experiment. The boron isotopic composition of each culture treatment is provided in  
194 Table 1. pH of the culture solutions was measured using a Metrohm, 826 mobile pH  
195 meter with glass electrode (Metrohm, electrode plus) calibrated to the total scale using  
196 TRIS and 2-aminopyridine buffer solutions (Dickson et al., 2007) adjusted to a  
197 salinity of 38.0 (Martinez-Boti et al. 2015). Total alkalinity ( $A_T$ ) samples (150 mL)  
198 were filtered on GF/F and measured potentiometrically using a Metrohm Tritando 80  
199 titrator and a Metrohm, electrode plus glass electrode (Dickson et al., 2007). 60 ml

200 samples was also taken at the start and end of incubations and poisoned with 10  $\mu\text{L}$  of  
201 saturated  $\text{HgCl}_2$  pending determination of dissolved inorganic carbon ( $C_T$ ). Samples  
202 were measured using an AIRICA (Marianda, Kiel) fitted with a Licor 6262 infra-red  
203 gas analyser. All parameters of the carbonate system were calculated from  $A_T$  and  $\text{pH}_T$   
204 (Hoppe et al., 2012) using the R package seacarb (Lavigne and Gattuso, 2013).

205

206

### 207 *Analysis of O. universa*

208 For simultaneous determination of the B isotopic composition and its concentration a  
209 Fiber Optics Spectrometer (Maya2000 Pro, Ocean Optics) was connected to the torch  
210 of a Thermo Finnigan Neptune multiple-collector inductively coupled plasma mass  
211 spectrometer (MC-ICP-MS) at the Leibniz University of Hannover. Laser ablation on  
212 reference material and samples was performed by an in-house build UV-femtosecond  
213 laser ablation system based on a regenerative one box femtosecond laser (Solstice  
214 Newport/Spectra Physics). A detailed description of the method used for the  
215 simultaneous determination of B concentration and  $\delta^{11}\text{B}$  of *O.universa* can be found  
216 in Kaczmarek et al. (2015a). A summary of the procedure is given below.

217

### 218 *Simultaneous determination of B concentration and $\delta^{11}\text{B}$*

219 The B intensity of a reference material corresponds to its known B concentration.  
220 Based on this relationship the unknown B concentration of a sample can be  
221 calculated. However, our measurements of the reference material (NIST SRM 610)  
222 and samples were not performed at the same laser repetition rate hence their B ratio is  
223 not proportional. The correction for different laser repetition rates was realized by the  
224 analysis of calcium in the reference material and in the sample because their Ca  
225 concentrations are known (NIST SRM 610: 8.45%,  $\text{CaCO}_3$ : 40%) using an optical  
226 spectrometer (Maya2000 Pro). More information on this procedure is provided by  
227 Longerich et al. (1996).

228

### 229 *Calcium analysis*

230 The Maya2000 Pro is a high-sensitivity fiber optical spectrometer. It has a measuring  
231 range between 250 to 460 nm with a resolution of 0.11 nm covering the first order  
232 emission lines of Mg II, Ca II, Sr II Ba II and Li II. It is equipped with a back-thinned

233 2D FFT-CCD detector, and a grating with a groove density of 1200 lines/mm. The  
234 optical fiber used is two meters long (attenuation of the photon flux is length  
235 dependent) connecting the spectrometer with the coupling lens at the end of the  
236 plasma torch of the MC-ICP-MS (Thermo Finnigan Neptune). Ca II ion lines were  
237 measured at a wavelength of 393.48 and 396.86 nm. At these wavelengths the Ca  
238 spectra shows no detectable interferences for the matrices used. The acquisition  
239 parameters were set to acquire 220 cycles per analysis with an integration time of 1 s  
240 for each cycle. Because of the stable Background (BG) signal detected for the first 40  
241 cycles, BG correction was done by subtracting its intensity from the intensity of the  
242 reference and the sample material.

243

#### 244 *Boron Isotope Analysis - 194 nm femtosecond laser ablation*

245 The in-house built laser ablation system is based on a 100 femtosecond Ti-sapphire  
246 regenerative amplifier system operating at a fundamental wavelength of 777nm in the  
247 infrared spectrum. Subsequent harmonic generations produce the wavelengths 389 nm  
248 in the second, 259 nm in the third and 194 nm in the fourth harmonic. The pulse  
249 energies measured with a pyroelectric sensor (Molelectron, USA) are 3.2mJ/pulse at  
250 777nm, 0.7 mJ/pulse at 259 nm, and 0.085 mJ/pulse at 194 nm. After the fourth  
251 harmonic generation stage, the 194 nm beam is steered by eight dichroic mirrors into  
252 a 8x objective (NewWave-Research, USA) and focussed onto the sample. Spot size  
253 was set to 50  $\mu\text{m}$  for the reference material and the samples. Within this spot an  
254 energy density of  $\sim 2 \text{ J/cm}^2$  is maintained. Reference material measurements were  
255 performed in raster mode (100 $\mu\text{m}$  x 100 $\mu\text{m}$ ) at 10 Hz, samples were ablated at 8-50  
256 Hz depending on B concentration.

257

#### 258 *Boron Isotope Analysis - Acquisition parameters*

259 All measurements are carried out in low mass resolution ( $\Delta m/m=350$  where m is the  
260 mass of the ion of interest and  $\Delta m$  is the mass difference between its 5 and 95% peak  
261 height). Compact discrete dynode multipliers (CDD, Thermo) are attached to faraday  
262 cups at the low site on L4 and the high site on H4. The low resolution mode is  
263 sufficient enough to resolve potential interferences from doubly charged ions due to  
264 the intrinsic high resolution in the low mass region. Possible interferences are the  
265 clusters of  $^{40}\text{Ar}^{4+}$  or  $^{20}\text{Ne}^{2+}$  which are well resolved to the background level. Prior to

266 each analytical session the instrument was tuned for optimal peak shape. Instrumental  
 267 operating conditions are reported in Table 2. All measurements were performed at  
 268 plateau voltage of the CDDs, which was checked prior to every analytical session.  
 269 Before the beginning of sample analysis, measurements of NIST SRM 610 were  
 270 continued until instrumental drift (due to warm-up) was less than 200 ppm over a  
 271 bracketing sequence duration of twelve minutes. Boron signal intensities of NIST  
 272 SRM 610 and samples were matched within 10% in signal intensity by adapting the  
 273 laser repetition rate. The acquisition parameters in static mode for analysis of NIST  
 274 SRM 610 and samples were set to acquire 200 cycles of 1 s integrations each. During  
 275 the first 40 cycles, the background signal was acquired whereas the remaining cycles  
 276 represent the sum of the background and the reference material, or the background  
 277 and the sample signals. A complete measurement consisting of 200 cycles of a single  
 278 reference material/sample took four minutes before the next sample was introduced.  
 279 For analysis we adopted the standard sample bracketing procedure and the B isotopic  
 280 composition is reported using the delta notation:

281

$$\delta^{11}B_{sample} (\text{‰}) = \left[ \frac{({}^{11}B/{}^{10}B)_{sample}}{\left( \frac{({}^{11}B/{}^{10}B)_{NIST610-1} + ({}^{11}B/{}^{10}B)_{NIST610+1}}{2} \right)} - 1 \right] \times 1000 \quad \text{Eq. (1)}$$

283

284 Where NIST 610-1 and NIST 610+1 refer to the analysis of the reference material  
 285 before and after the sample. The uncertainty of the samples was calculated according  
 286 to:

287

288

$$2SE_{\delta^{11}B_{sample}} (\text{‰}) =$$

$$\sqrt{\left( \frac{SE}{({}^{11}B/{}^{10}B)_{NIST-1}} \right)^2 + \left( \frac{SE}{({}^{11}B/{}^{10}B)_{sample}} \right)^2 + \left( \frac{SE}{({}^{11}B/{}^{10}B)_{NIST+1}} \right)^2} \times 2 \times 1000 \quad \text{Eq. (2)}$$

290

291 Where  ${}^{11/10}B$  ratios represent mean values of the reference material and the sample  
 292 calculated from one measurement, respectively (based on 160 cycles) and SE  
 293 represents the standard error of the  ${}^{11/10}B$  ratios. Due to the natural inhomogeneity of  
 294 the samples the analytical uncertainty is represented best by repeated measurements  
 295 of the homogenous reference material given by:

296

$$\delta^{11}B_{NIST610}(\text{‰}) = \left[ \frac{{}^{11/10}B_0}{\left( \frac{{}^{11/10}B_{-1} + {}^{11/10}B_{+1}}{2} \right)} - 1 \right] \times 1000 \quad \text{Eq. (3)}$$

298

299 Where the measurements of the  $({}^{11/10}\text{B})_{-1}$  and  $({}^{11/10}\text{B})_{+1}$  ratios of NIST 610 were  
 300 performed before and after the measurement of  $({}^{11/10}\text{B})_0$ , respectively. For the  
 301 determination of the analytical uncertainty and external reproducibility all  
 302 measurements of NIST 610 performed between each sample measurement were taken  
 303 into account. On average the analytical uncertainty and external reproducibility is  
 304 0.66‰.

305

#### 306 *Conversion of $\delta^{11}B_{O.universa}$ to seawater scale*

307 Due to the B addition to our culture media, the  $\delta^{11}B_{seawater}$  shifted from 37.95 to on  
 308 average 4.66 ‰. Therefore, the  $\delta^{11}B_{O.universa}$  shifted accordingly. In order to compare  
 309 our *O. universa* data to published values (Fig. 3A), the measured  $\delta^{11}B$  was converted  
 310 to seawater scale using (Zeebe & Wolf-Gladrow, 2001):

311

$$\delta^{11}B_c = \alpha_{sw-msw} \times \delta^{11}B_m + \varepsilon \quad \text{Eq. (4)}$$

313

314 Where  $\varepsilon$  is  $(\alpha_{sw-msw} - 1) \times 1000$ ,  $\delta^{11}B_c$  represents the converted  $\delta^{11}B$  for the measured  
 315 value ( $\delta^{11}B_m$ ),  $\alpha_{sw-msw}$  is a fractionation factor expressing the difference between the  
 316 natural seawater and manipulated seawater:

317

$$\alpha_{sw-msw} = (\delta^{11}B_{sw} + 10^3) / (\delta^{11}B_{msw} + 10^3) \quad \text{Eq. (5)}$$

319

#### 320 *Statistics:*

321 Lamtool was used for analysis and background correction of the  $\delta^{11}B$  data. All other  
 322 statistics were carried out using R (R Core Team, 2008). Error bars represent  $\pm 2\sigma$   
 323 errors, correlations were calculated by linear regression.

324

#### 325 **Results:**

326 *B/Ca ratios:*

327 The B/Ca ratio of *O. universa* shows a strong negative correlation ( $R^2 = 0.96$ ) with  $C_T$   
328 irrespective of the  $pH_T$  of the culture media (Fig 2A). It is also correlated to  $[CO_2]$  but  
329 to a lesser extent ( $R^2 = 0.64$ ; Fig 2C). B/Ca also decreases with increasing  $[CO_3^{2-}]$  in  
330 specimens grown under a  $pH_T$  of 8.05, (Fig 2E). However, the B/Ca ratio of  
331 specimens grown under lower  $pH_T$  values (7.9 and 7.7) is negatively offset from the  
332 relationship found at  $pH_T$  8.05 and the overall correlation of B/Ca and  $[CO_3^{2-}]$  is very  
333 low ( $R^2 = 0.2$ ; Fig 2E). Of all the carbonate species, the B/Ca ratio exhibits the best,  
334 negative, relationship with increasing  $[HCO_3^-]$ , irrespective of the  $pH_T$  of the culture  
335 medium ( $R^2 = 0.96$ ; Fig 2G). Plotted against the ratio of  $[B(OH)_4^-]$  over each of the  
336 carbon species (Fig 2B, D, F, H), the correlations are high for all combinations but  
337 highest for  $[B(OH)_4^-]/[CO_3^{2-}]$ .

338

339

340 *Boron isotopic fractionation ( $\delta^{11}B$ ):*

341 Single, measured  $\delta^{11}B$  values of *O. universa* are given in Supplementary Table 1,  
342 errors are calculated according to Eq. (2). Mean and converted values using Eq. (4)  
343 and Eq. (5) are shown in Fig. 3A and Table 3. The fractionation of boron isotopes in  
344 the shells of *O. universa* is dependent on the pH of the culture medium, increasing  
345 with  $pH_T$  from 15‰ at  $pH_T$  7.7 to 18.8‰ at  $pH_T$  8.05. These values are close to the B  
346 fractionation curve of  $B(OH)_4^-$  obtained for artificial seawater by (Fig 3A; Klochko et  
347 al., 2006).  $\delta^{11}B$  increases slightly with increasing  $[CO_3^{2-}]$  at constant  $pH_T$  (Fig 3B).  
348 However, the data are all within analytical error, suggesting that there is no significant  
349 effect of  $[CO_3^{2-}]$  on  $\delta^{11}B$ .

350

351

352

353 **Discussion:**354 *B/Ca:*

355 Foster (2008) identified  $[CO_3^{2-}]$  as having a major control on B/Ca in samples of  
356 foraminifera from down core samples and core tops. A similar conclusion was  
357 reached by Allen et al. (2011) for *O. universa*. These authors demonstrated a trend of  
358 decreasing B/Ca with increasing pH and  $[CO_3^{2-}]$ ; however, due to the co-variations of  
359 the carbonate system in natural seawater it is difficult to identify the differential

360 effects of the individual parameters. Experimentally decoupling  $\text{pH}_T$  from other  
361 parameters of the carbonate system using modified seawater media allows us to  
362 decouple the relationships and identify the controlling carbon species. Our results  
363 demonstrate that the amount of boron incorporated into *O. universa* calcite is a  
364 function of  $C_T$  (Fig. 2A). As  $C_T$  increases, B/Ca decreases, suggesting that  $\text{B(OH)}_4^-$   
365 competes with carbon species for inclusion into the calcite lattice. When B/Ca ratios  
366 are plotted against  $[\text{CO}_2]$ , the relationship is similar to that of  $C_T$ , however only <1%  
367 of  $C_T$  is in the form of  $\text{CO}_2$  so this species is unlikely to have a major control on  
368 boron incorporation. The remaining >99% is ~10%  $\text{CO}_3^{2-}$  and ~90%  $\text{HCO}_3^-$  (Zeebe  
369 and Wolf-Gladrow, 2001). Due to the strong correlation of the B/Ca ratio and  
370  $[\text{B(OH)}_4^-]/[C_T]$ , one could argue that foraminifera utilize both  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$  as  
371 substrate for calcification and, therefore, that  $C_T$  is the factor controlling the B/Ca  
372 ratios. However, because  $[\text{HCO}_3^-]$  and  $[\text{CO}_3^{2-}]$  in our treatments, increase and  
373 decrease with decreasing  $\text{pH}_T$ , respectively (Table 1), we can distinguish between  
374 bicarbonate and carbonate ion control over the B/Ca ratio.

375  
376 At constant  $\text{pH}_T$ , the relationship between B/Ca and  $[\text{CO}_3^{2-}]$  (Fig. 5.1C) supports the  
377 hypothesis of competition between  $\text{CO}_3^{2-}$  and  $\text{B(OH)}_4^-$ . However, when  $[\text{CO}_3^{2-}]$  is  
378 held constant and  $\text{pH}_T$  is decreased, B/Ca significantly decreases despite the fact that  
379  $[\text{CO}_3^{2-}]$  remains more or less constant (Fig 2 E, Table 1). If the same relationships are  
380 examined for B/Ca and  $[\text{HCO}_3^-]$  a strong correlation between  $[\text{HCO}_3^-]$  and B/Ca is  
381 observed for both, the absolute concentration of  $\text{HCO}_3^-$  (Fig. 2G) and also for the ratio  
382 of  $[\text{B(OH)}_4^-]/[\text{HCO}_3^-]$  with no effect of changing  $\text{pH}_T$  (Fig. 2H). The close correlation  
383 between  $[\text{CO}_3^{2-}]$  and B/Ca at constant  $\text{pH}_T$  can be explained by the corresponding  
384 increases in  $[\text{HCO}_3^-]$  in these treatments (Table 1).

385  
386 In agreement with our results, the study of Allen et al. (2012) investigated the effects  
387 of decoupling pH and the carbonate system on B/Ca and suggest that  $\text{B(OH)}_4^-$   
388 competes with carbon species for inclusion into the calcite lattice in three planktonic  
389 species *Globigerinoides sacculifer*, *Globigerinoides ruber*, and *Orbulina universa*.  
390 However, analysis of planktonic foraminifera from core tops revealed correlation  
391 between B/Ca and exclusively  $\text{B(OH)}_4^-/\text{HCO}_3^-$  (excluding  $\text{B(OH)}_4^-/\text{CO}_3^{2-}$  and  $\text{B(OH)}_4^-$   
392  $/C_T$ ). Yu et al., (2007). A recent study by Kaczmarek et al. (2015b) shows the same

393 competition between  $\text{B(OH)}_4^-$  and  $\text{HCO}_3^-$  in the benthic species *Amphistegina*  
 394 *lessonii* cultured in a pH- $[\text{CO}_3^{2-}]$  decoupled seawater. The observation that B/Ca is  
 395 driven by  $\text{B(OH)}_4^-/\text{HCO}_3^-$  and not related to  $\text{CO}_3^{2-}$  only becomes visible at higher pH  
 396 (8.6) when  $[\text{B(OH)}_4^-]$  is sufficiently high (see Fig. 6 and Table S1 in Kaczmarek et al.,  
 397 2015b). Below 8.6 foraminiferal B/Ca also correlates with  $\text{B(OH)}_4^-/\text{CO}_3^{2-}$ .

398

399 The finding that  $\text{B(OH)}_4^-/\text{HCO}_3^-$  is controlling on boron incorporation in *O. universa*  
 400 calcite is also in agreement with the hypotheses of Hemming and Hanson (1992) who  
 401 suggested that only  $\text{B(OH)}_4^-$  is incorporated into marine carbonates with the partition  
 402 coefficient defined below.

403

$$404 \quad K_D = \frac{[\text{B/Ca}]_{\text{solid}}}{[\text{B(OH)}_4^- / \text{HCO}_3^-]_{\text{seawater}}} \quad \text{Eq. (6)}$$

405

406 To summarize, based on our study, we can eliminate a control by  $[\text{CO}_3^{2-}]$  but cannot  
 407 exclude  $[\text{B(OH)}_4^-/\text{CO}_3^{2-}]$ . By comparison to the B/Ca control in the benthic  
 408 foraminifer *Amphistegina lessonii* (Kaczmarek et al., 2015), we assume B/Ca in  
 409 planktonic foraminifera is also a function of  $[\text{B(OH)}_4^-/\text{HCO}_3^-]$ .

410

411 *Boron isotopic fractionation ( $\delta^{11}\text{B}$ ):*

412 As the various species of inorganic carbon and  $\text{pH}_T$  are tightly linked, it is still to be  
 413 experimentally demonstrated, beyond doubt, whether only  $\text{pH}_T$  and/or the  
 414 concentration of one or several carbonate species might have an effect on  $\delta^{11}\text{B}$ . The  
 415 results for treatments with varying  $\text{pH}_T$  and constant carbonate ion concentration  
 416 displayed the same relationship as those from the calibration curve for *O. universa*  
 417 produced by Sanyal et al. (1996) but the absolute values for a given  $\text{pH}_T$  are slightly  
 418 lower by approximately 1 to 2‰ when compared to the values corrected to the  
 419 fractionation factor suggested by Klochko et al. (2006) (Zeebe et al., 2008). The  
 420 effects of the unnaturally high  $C_T$  and  $A_T$  values in the treatments cannot be  
 421 discounted as the cause of this difference, although it is unlikely because the  $\delta^{11}\text{B}$   
 422 values proved to be robust when a range of  $[\text{CO}_3^{2-}]$  was used. The values produced for  
 423  $\delta^{11}\text{B}$  in this study match closely with the values for artificial seawater given by  
 424 Klochko et al. (2006). This is caused by the suppression of the vital effects imposed

425 by *O. universa*. Theoretical considerations demonstrate that at 10X boron  
426 concentration compared to natural seawater, vital effects are suppressed and the  
427 isotopic value of biogenic calcite approaches the value of the borate species being  
428 taken up (Zeebe, 2003). This was confirmed by the comparison of the boron isotopic  
429 values of *O. universa* grown at low and high light (Hönisch et al., 2003) and supports  
430 the notion that borate is indeed the species being taken up. There is no effect of  
431 varying  $[\text{CO}_3^{2-}]$  on  $\delta^{11}\text{B}$  of samples grown at the same pH but, most importantly, in  
432 light of the results obtained for the B/Ca ratio, there is also no effect of  $[\text{HCO}_3^-]$  (Fig.  
433 3C).

434

435

436 *Proxy implications:*

437 Based on our results and other culture studies, it becomes clear that despite strong  
438 biological effects on the ambient carbonate chemistry (Köhler-Rink and Kuhl, 2001;  
439 Köhler-Rink and Kühl, 2000; Rink et al., 1998; Wolf-Gladrow et al., 1999; Zeebe et  
440 al., 2008), the boron isotopic composition and the B/Ca are faithful predictors of pH  
441 and bicarbonate ion concentration, respectively. Our results provide strong evidence  
442 that  $[\text{HCO}_3^-]$  is recorded in the B/Ca ratio. A wide range of  $[\text{HCO}_3^-]$  was necessary to  
443 facilitate de-coupling the carbonate system from  $\text{pH}_T$ , however the high  $[\text{HCO}_3^-]$  in  
444 several of these treatments are unrealistic for natural seawater systems, particularly  
445 paleo-systems which exhibit lower  $[\text{HCO}_3^-]$  than present day oceans (calculated from  
446 values given in Zeebe, 2012) and more environmentally-relevant values should be  
447 used for future calibration experiments. The proxy should therefore be ground-truthed  
448 using core top samples. The correlation of the B/Ca ratio to  $[\text{HCO}_3^-]$  rather than to  
449  $[\text{CO}_3^{2-}]$  might have some implications for existing paleo-carbonate chemistry  
450 reconstructions based on this proxy such as the study by Foster (2008) and that of Yu  
451 et al. (2014), since the same relationship probably holds for benthic foraminifers as  
452 for planktonics.

453

454 A sound understanding of the effects of past carbon perturbations becomes  
455 increasingly urgent in an age where anthropogenic activities are producing such rapid  
456 changes in global climate (Bijma et al., 2013; Knoll and Fischer, 2011). The  
457 usefulness of biogeochemical proxies to reconstruct paleoceanographic conditions is

458 well established for environmental parameters such as temperature and salinity  
459 (Wefer et al., 1999) but uncertainties remain for proxies related to pH and the  
460 carbonate system (Allen and Honisch, 2012; Hönisch et al., 2007; Katz et al., 2010;  
461 Pagani et al., 2005). This study confirms the robustness of  $\delta^{11}\text{B}$  as an independent pH  
462 proxy and adds further weight to the growing body of evidence that B/Ca in  
463 planktonic foraminiferal calcite may be used as an independent proxy for  $[\text{HCO}_3^{2-}]$   
464 (Yu et al. 2007), thereby allowing researchers to fully constrain the carbonate system.
