Figure S3. Lidar derived images: shaded relief of topography and canopy height model (CHM), at 1 m resolution. Mean canopy height (MCH), standard deviation of canopy height and elevation range are reported.

15 **S.1 Estimating aboveground biomass from forest inventories.**

16
17 For trees with no height measurement, a site specific DBH height model was used to infer tree
18 height in each site, as described in previous studies (Feldpauch et al., 2012; Meyer et al., 2013,).
19 Wood density was extracted from the global wood density database for tropical trees (Chave et
20 al., 2009; Zanne et al., 2009) for each tree, based on its level of botanical identification (species,
21 genus, family). Trees with no botanical identification were assigned the average wood density of
22 the plot. Average wood density of each site was calculated as the unweighted average of all trees
23 within a site, or was taken from a previous study in the case of Cotriguaçu (Fearnside, 1997).
24 Average wood density of large trees was calculated as the unweighted average of trees with
25 $DBH \geq 50$ cm in each site. Tree level AGB was aggregated at the plot level using a commonly
26 used allometric regression model for moist tropical forests (Eq. (S1), Chave et al., 2005), except
27 for La Selva and Chocó, for which a model for wet tropical forest (Eq. (S2), Chave et al., 2005)
28 and a local allometric model (Eq. (S3), Duque et al., 2017) were used, respectively.

$$29 \quad AGB_{moist} = 0.0509 \times \rho DBH^2 H \quad (S1)$$

$$30 \quad AGB_{wet} = 0.0776 \times (\rho DBH^2 H)^{0.940} \quad (S2)$$

$$31 \quad AGB_{Chocó} = 0.089 \times (\rho DBH^2 H)^{0.951} \quad (S3)$$

32 where trunk diameter (DBH in cm) is measured during the inventory, tree height (H , in m) is
33 either measured in the field or estimated from a local DBH – H model, and specific gravity or
34 wood density (ρ in $g\ cm^{-3}$) is known for each tree. AGB (in kg of dry biomass) of individual
35 trees estimated using the former equations was used to calculate plot level AGB density ($Mg\ ha^{-1}$)
36 by summing over the biomass of all stems within each plot. Ground estimated AGB density is
37 henceforth referred to as AGB_{inv} . Estimating AGB with these allometric models has been

38 reported to have a standard error of 12.5 % when using height as a parameter, against 19.5 %
39 when height is not available (Chave et al., 2005).

40

41 **S.2 Local estimates of AGB using MCH**

42 We estimated AGB locally for each of the nine sites in order to find the best height threshold for
43 LCA in all sites, in addition to the information provided by the four calibration sites (see Fig. 3).
44 Mean canopy height (MCH) is a good predictor of AGB provided that the regression model is
45 calibrated locally. It was calculated by averaging all the canopy height model pixels falling in an
46 area of interest. Here, we calculated a locally calibrated AGB map of each site from MCH using
47 the following model form (Eq. (3), Asner and Mascaro, 2014).

$$48 \quad AGB_{Local} = aMCH^b + \epsilon \quad (S4)$$

49 where AGB_{Local} is the aboveground biomass estimation derived from Lidar data, a is a scaling
50 constant, which is expected to depend significantly on forest type and stand level wood density,
51 b is a power law exponent and $\epsilon \sim N(0, \sigma^2)$ represents the uncertainty in measurements. All
52 coefficients are presented in Table S1. We inferred the model parameters directly for the sites
53 where AGB_{inv} of 1 ha plots was available (La Selva, BCI, Paracou and Nouragues). For Chocó
54 and Antimary, we developed models based on 0.25 ha plots and 50 m x 50 m pixels of Lidar data
55 and after estimating AGB_{Local} , aggregated the image to 1 ha or 100 m pixels. For the remaining
56 sites of the Central Amazon (Cotriguaçu, Manaus and Tapajós), we developed a model based on
57 existing data in Manaus and Tapajós from a previous study, derived from airborne and
58 spaceborne Lidar (see Lefsky et al., 2007). This model may have larger uncertainty in estimating
59 biomass compared to our site specific model, but we here assume that all 1 ha scale AGB_{Local}
60 estimates have approximately similar uncertainties.

85 **Figure S4.** Distribution of R^2 between DBH thresholds and AGB_{Local} in 1 ha subareas (a) and AGB_{inv} in 1 ha inventory
86 plots (b). DBH was calculated from tree height using Chave's E factor model (Chave et al., 2014)

87

88

89 **S.3 LCA and ground data**

90 We looked at the relation between LCA and other stand level metrics: AGB_{inv} of large trees,
91 stand basal area, Lorey's height (H_L), and the number of large trees. Lorey's height is defined by

92 $H_L = \frac{\sum_{i=1}^N BA_i H_i}{\sum_{i=1}^N BA_i}$ where H_i is the height of stem i , and BA_i is the basal area of stem i . Weighting

93 tree height with basal area increases the relative importance of large trees in a stand (Lefsky,
94 2010).

95 There was a significant correlation between LCA and AGB_{inv} in all calibration sites ($R^2_{max} = 0.77$

96 in La Selva), and even more so between LCA and AGB_{inv} of large trees ($R^2_{max} = 0.83$ in La

97 Selva) (Table S4). LCA correlated with Lorey's height, especially at La Selva but less so at

98 Nouragues ($R^2_{LaSelva} = 0.86$, $R^2_{Nouragues} = 0.21$). We also found that LCA and total basal area are

99 correlated. The relationship between LCA and the number of large trees is significant in all sites,

100 but it is lower than other structural metrics in Paracou ($R^2 = 0.32$). Among study sites, La Selva

101 and BCI show higher correlations between LCA and ground derived metrics. The strong

102 correlation of LCA with plot level AGB_{inv} as well as with AGB_{inv} of large trees suggested that a

103 model based on LCA can be used as an estimator of AGB.

104

105 **Table S4** : Coefficients of correlation (R^2) between LCA and ground data derived metrics : AGB_{inv} , AGB_{inv} of
 106 trees ≥ 50 cm DBH, basal area, Lorey's height and number of large trees in BCI, La Selva, Nouragues and Paracou.

	BCI	La Selva	Nouragues	Paracou
AGB_{inv}	0.64	0.77	0.48	0.64
AGB_{50}	0.68	0.83	0.47	0.69
BA	0.63	0.53	0.41	0.43
LH	0.57	0.86	0.21	0.63
N_{70}	0.64	0.76	0.46	0.32

107

108

109 **S.4 Contribution of Large Trees to AGB_{inv}**

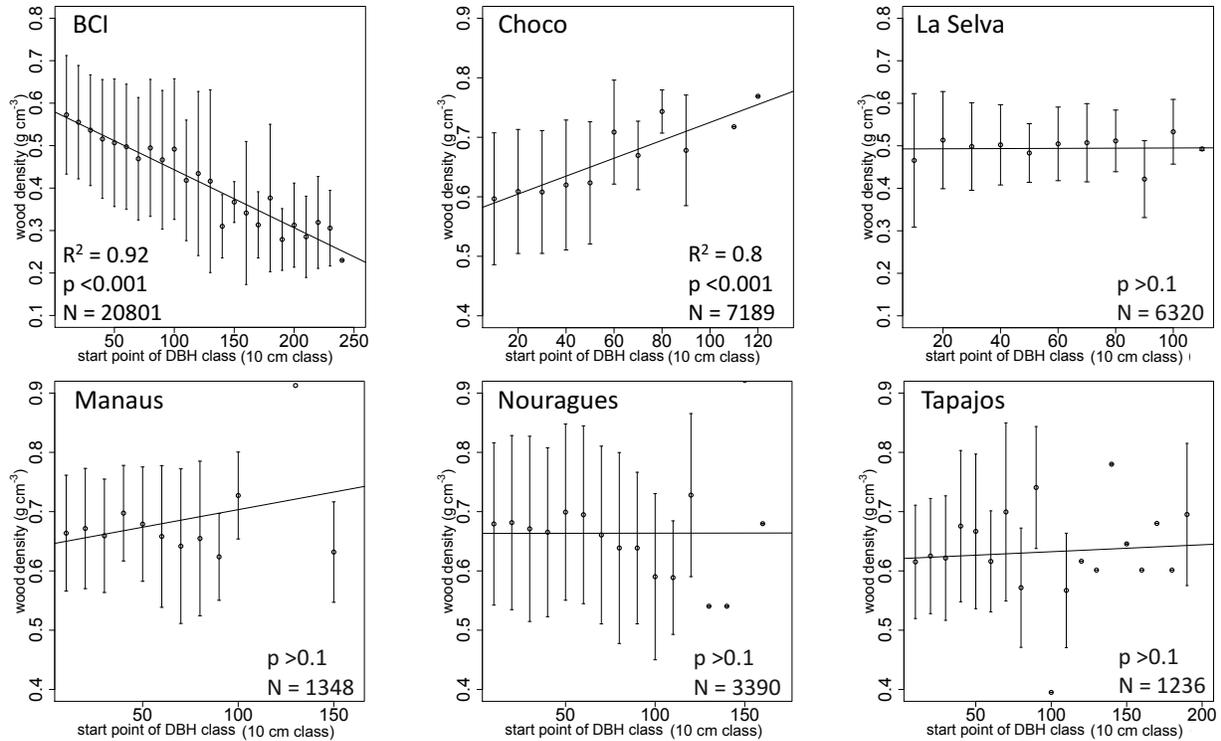

110 First, we explored the role of wood density as a key variable in allometric models to scale the
111 tree volume or size to AGB_{inv} (Brown et al., 1989; Chave et al., 2005; Chave et al., 2014,
112 Ngomanda et al., 2014). We examined the variations of wood density as a function of DBH
113 classes in all sites and for all trees greater than 10 cm arranged in 10 cm DBH bins.

114 We then assessed the proportion of large trees by examining the DBH frequency distribution of
115 trees at different sites using the field inventory data, and compared it to the distribution of
116 AGB_{inv} for the same DBH ranges, using 1 cm bins to create DBH classes.

117 **Results**

118 DBH and wood density: At BCI, mean wood density decreased significantly with increasing
119 DBH ($p < 0.001$, $R^2 = 0.92$), which is consistent with the results of a previous study (Chave et al.,
120 2004). On the contrary, at Chocó, mean wood density increased significantly with increasing
121 DBH ($p < 0.001$, $R^2 = 0.8$). No significant trend was found at the other study sites (Fig. S5). These
122 results show that stand average wood density and wood density of large trees are not
123 significantly different in four sites and can therefore be used interchangeably in a model using
124 these data. However, using one or the other will have an impact on the results of a model
125 calibrated using data from BCI or Chocó. Mean wood density of trees ≥ 50 cm is 0.49 in BCI (vs.
126 stand average $WD = 0.54 \text{ g cm}^{-3}$) and 0.66 in Chocó (vs. stand average $WD = 0.60 \text{ g cm}^{-3}$).

127

128

129 **Figure S5.** Wood density and DBH classes in BCI, Chocó, La Selva, Manaus, Nouragues and Tapajós. The decrease
 130 in mean wood density is significant in BCI ($p < 0.001$, $R^2 = 0.92$). The increase in mean wood density is significant in
 131 Chocó ($p < 0.001$, $R^2 = 0.8$) but there is no significant wood density change across DBH classes in the other sites
 132 ($p > 0.1$). Points with no standard deviation bars mean that only one tree was present in the class.

133

134 We found that using mean wood density of trees ≥ 50 cm DBH in our LCA model gives slightly
 135 better results than using mean wood density (see Eq. (3)), with R^2 of 0.78, RMSE of 45.34 Mg
 136 ha^{-1} and bias of -0.36 Mg ha^{-1} .

137

138 DBH and AGB : The relationship between AGB_{inv} and the DBH frequency distribution was

139 similar in BCI, La Selva, Nouragues and Tapajós (Fig. S6). In these sites, more than 50 % of the

140 total AGB_{inv} was contributed by around 5 % (between 3 % and 6 %) of the stems, corresponding

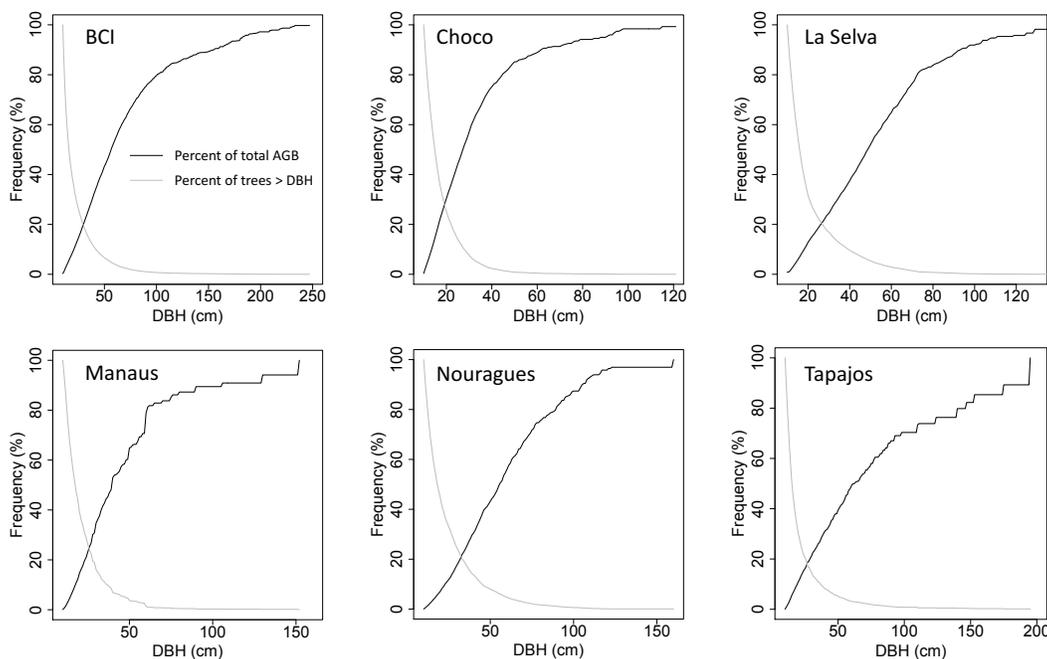

141 to a threshold DBH of 58 cm, 50 cm, 55 cm and 61 cm respectively for the four study sites.

142 Similar results were found in a recent study focusing on the contribution on large trees to AGB

143 in Central Africa (Bastin et al., 2015). Also, 80 % of the AGB stock was in trees with $\text{DBH} \geq 30$

144 cm DBH at BCI, 26 cm at La Selva, 32 cm at Nouragues and 29 cm at Tapajós, which echoes

145 results published on BCI (Chave et al., 2001). These represent only 20 % of the total number of
 146 trees in each site (only 15 % in Tapajós). Chocó and Manaus had far less large trees, 50 % of
 147 their total AGB_{inv} being explained by respectively 10 % and 7 % of the total number of trees,
 148 corresponding to a DBH greater than only 28 cm and 40 cm. In these two sites, 80 % of AGB_{inv}
 149 is found in trees above 17 cm and 23 cm, respectively, representing 37 % and 31 % of their total
 150 number of trees. These findings corroborate with previous studies from other sites and suggests
 151 that large trees can explain AGB variations and could potentially be used to estimate biomass
 152 without having to measure all trees in a plot (Bastin et al., 2015; Slik et al., 2013). Note that
 153 some ground data from Manaus and Nouragues were included in Silk et al.'s dataset).

154
 155 **Figure S6.** Cumulation of of AGB_{inv} and of number of trees (total number of trees ≥ 10 cm DBH) as a function of
 156 DBH in BCI, Chocó, La Selva, Manaus, Nouragues and Tapajós plots.
