Anonymous Referee #1

The authors conducted a field experiment to assess how the use of ethylene biosynthesis inhibitor (AVG) would alleviate the inhibitor y effects of ethylene from plants due to drought stress to methane oxidation of soil microbes. Their results showed that adding AVG could increase soil methane oxidation rates compared to control, and thus they concluded that AVG application can increase soil methane oxidation process under moisture stressed conditions. I found this manuscript was straightforward and well written. The topic falls within the scope of the journal. But I think this paper is more suitable for a short communication, as the paper is too short and data presented here was very limited. I suggest the authors can modify it to a short communication.

R: Many thanks for your positive comments. We have asked the journal manager to change the type of this manuscript into 'Technical Note', a kind of short communication for this journal.

Some minor points are here.

1. L67-70 Rephrase it. Too long to understand.

R: It has been revised. Lines 72-76

2. L111-116 How many gas sampling was conducted to measure CH4 oxidation rates in one jar? How about the coefficient for linear regression? It's better to show gas concentration over time for different treatments in this study.

R: We conducted two gas sampling at the beginning and the end of the incubation. Then soil methane oxidation rates in each jar were calculated from differences in the headspace CH_4 concentration over the incubation time. We cannot provide the changes in CH_4 concentration and we cannot calculate the linear regression of soil CH_4 oxidation rates over time, but we acknowledge that these data will make these results more interesting. Lines 126-128

3. L135 "CH_4 methane oxidation"

R: Thanks. It has been changed into 'CH_4 oxidation'. Line 152

4. L161-164 Can excessive irrigation directly reduce aerobic methane oxidation as the authors proposed in L148-152?

R: Yes, it might be possible. However, it would be expected that the combination of irrigation and AVG would produce CH_4 oxidation rates either the same, or potentially greater than, those observed for AVG alone. In this study, we did not find this case, so the explanation for the significant interaction remains unknown. A further study are needed to investigate the effects of plant, soil and microbial interactions under drought stress. Lines 183-190

Technical Note

Manipulating interactions between plant stress responses and soil methane oxidation rates

30 **Abstract**

31

32 It has recently been hypothesised that ethylene, released into soil by stressed plants,

33 reduces the oxidation of methane by methanotroph. To test this, a field trial was

34 established in which maize plants were grown with and without soil moisture stress,

35 and the effects of addition aminoethoxyvinylglycine (AVG; an ethylene biosynthesis

36 inhibitor), and biochar (increases soil water holding capacity and reduces plant stress)

37 were determined following the static incubation of soil samples. AVG increased

38 methane oxidation rates by 50% (P=0.039), but only in the absence of irrigation. No

39 other treatment effects were observed. This result provides evidence for a positive

40 feedback system between plant stress, ethylene production, and impacts on

41 methanotrophic activity.

1 Introduction

The atmospheric concentration of methane (CH_4) has almost tripled over the past 150 years, making a substantial contribution to climate change (Forster et al., 2007). Aerobic soils provide an important habitat for methanotrophic bacteria, and provide the only significant biological sink for atmospheric CH_4 (20-45 Tg CH_4 yr^{-1}) (Forster et al., 2007). However, CH_4 uptake by these soil ecosystems can be impacted by environmental stress (Kolb, 2009). A common plant physiological response to ecological stress, such as drought, is the production of ethylene (Morgan and Drew, 1997). In soils, however, ethylene maybe inhibitory to methanotrophic activity (Jäckel et al., 2004; Pierek et al., 2006; Zhou et al., 2013), and thereby reduce CH_4 oxidation. This potential interaction needs to be understood, as it may constitute an important positive feedback loop between climate disruption, soil ecosystem disturbance, and reduced CH_4 removal from the atmosphere (Bousquet et al., 2006; Zhou et al., 2013).

To test our previous hypothesis that drought-induced *in planta* ethylene production reduces soil CH_4 oxidation rates (Zhou et al., 2013), we manipulated plant stress responses by adding the ethylene biosynthesis inhibitor aminoethoxyvinylglycine ([S]-trans-2-amino-4-(2-aminoethoxy)-3-butenoic acid hydrochloride; hereafter AVG) (Boller et al., 1979). In addition, the study tested the hypothesis that addition of biochar to soils may result in increased water holding capacity, reducing drought stress and thereby acting as a potential tool to maintain CH_4 oxidation (Karhu et al., 2011). This is illustrated conceptually in Fig. 1, in which the application of irrigation (IR) and biochar (BC) are able to maintain rates of CH_4 oxidation by reducing moisture stress and therefore ethylene production, whereas AVG prevents the production of ethylene after the plant experiences stress.

2 Material and methods

2.1 Study site

The study site was located in the Bjelke-Petersen *Research Station* at Kingaroy (26.53° S, 151.83° E) in the South Burnett Region of Queensland, Australia. Precipitation averages 789 mm per annum with erratic summer droughts frequent in the region. Soil at the field trial site soil is an acidic red ferrosol (pH 5.5) with high cation

89   exchange capacity (Isbell, 1993). The site has a long history of cultivation, supporting

90   peanut and maize rotations with winter fallows.

91   **2.2 Experiment design and management**

92   A full factorial, split plot design field trial was established as follows: two IR

93   treatments (IR and no IR) × two BC treatments (BC at 9.2 t ha^{-1} and no BC) × two

94   ethylene suppression treatments (AVG and no AVG). Each treatment had five replicates,

95   producing a total of 40 plots. Due to practical concerns regarding application and

96   maintenance, the IR treatments were established in two discrete areas that were spanned

97   by five blocks. A schematic of the trial site is given in the supplementary information

98   (Fig. S1).

99   The BC treatment was established through application of peanut shell BC to the

100   surface of the planting zone (~450 mm wide strip each row) in early 2013. The BC was

101   incorporated into the soil with a rotary hoe to a depth of 200 mm. The chemical

102   properties of the peanut shell BC are provided in the supplementary information (Table

103   S1).

104   The site was machine planted with maize cultivar Pioneer 32p55 (Dupont Pioneer

105   Australia) at a density of approximately 4 plants m^{-2} in late January, 2014. Compound

106   fertiliser (N:P$_2$O$_5$:K$_2$O 11.9:14.1:9.9) at 180 kg ha^{-1}, and urea at 100 kg ha^{-1}, were

107   applied at sowing. Trickle tapes, installed into plots receiving IR, were used to distribute

108   water equivalent to ~50 mm of rainfall whenever there was a continuous dry spell for

109   two weeks throughout the growing season (late January to late June).

110   To reduce the *in planta* production of ethylene, the commercial plant growth

111   regulator ReTain (containing 15% AVG, Valent Bioscience Cooperation, Walnut Creek,

112   CA, USA) was sprayed onto the crop four times from mid-April to mid-June (the peak

113   maize growth window) at intervals of three weeks. During each event, the treated rows

114   of maize received approximately 750 ml of ReTain solution (prepared at the label rate

115   of 1 g ReTain l^{-1} water) directly to the surface of the plants.

116   **2.3 Sample collection and analysis**

117   In late June 2014, six soil cores from 0 - 100 mm depth were collected from the maize

118   rooting zone of each plot using a 30 mm diameter soil auger. All samples were collected

from the two middle rows of maize in each plot, and the six soil cores from within each plot bulked to a single plot sample. After sieving to 2 mm, a 50 g (fresh mass) subsample of each sample was set aside for CH_4 oxidation rate measurements and the remaining material dried at 105°C for 48 hours to determine soil moisture content.

Soil CH_4 oxidation rates were determined using the laboratory incubation. Briefly, about 20 g soil subsamples were incubated in 1-litre glass jars at ambient atmospheric CH_4 concentration (assumed to be 1.9 ppm) for one week in the dark at 25°C. Headspace gas samples (approximately 30 ml) were collected through a rubber septum in the jar lid at the beginning and the end of the incubation, and concentrations of CH_4 determined using GC-FID (GC-2010 Plus, Shimadzu, Japan). The CH_4 oxidation rates in each jar were calculated from differences in the headspace CH_4 concentration over the incubation time (Zhou et al., 2008), and adjusted to soil dry weight. Standards were measured once every 10 samples; the coefficient of variation in CH_4 oxidation rate was less than 5% and control jars had ambient CH_4 concentrations.

2.4 Statistical analysis

Statistical analysis was carried out in R-3.2.3 (Zhou et al., 2017) using a multi-factor ANOVA model incorporating an error structure accounting for the split-plot design associated with the non-random assignment of the IR treatment. The multi-comparison analysis methods provided in the "easyanova 4.0" R package was used to test for treatment interactions.

3 Results

Over the course of the field trial, five dry spells occurred. Irrigation to the IR-plots resulted in delivery of 250 mm more water to this treatment than the controls. This resulted in significantly increased soil moisture (P<0.001) in IR soils (18.9%) compared with the non-irrigated soils (15.4%) at sampling time. Neither the AVG or BC treatments had any effect (P>0.05) on soil moisture.

No significant main effects were observed, but a significant interaction between irrigation and AVG application was detected (Table 1). Exploration of this interaction with multi-comparison analysis determined that CH_4 oxidation rates were increased by 50% following AVG application (P=0.039), but only in the absence of IR (Fig. 2). The

149 addition of biochar had no effect on CH_4 oxidation rates either as a main or interactive
150 effect.

4 Discussion

152   The increase in CH4 oxidation with the AVG treatment either alone or in combination
153 with the BC treatment aligns with past studies assessing the effect of increased ethylene
154 concentrations on soil CH_4 oxidation rates (Jäckel et al., 2004; Xu et al., 2008). This
155 response also supports the hypothesis that *in planta* ethylene production in response to
156 stress decreases the capacity of soil to support methanotrophic activity (Zhou et al.,
157 2013).

158   The lack of effect of BC on CH_4 oxidation is at odds with the results of previous
159 work (e.g. Karhu et al., 2011; Kim et al., 2017). However, BC added in this study had
160 no influence on soil moisture content, and this is proposed to be a key mechanism for
161 BC to support CH_4 oxidation in drought conditions (Karhu et al., 2011). The reason
162 why BC addition did not result in increased soil moisture in this case is unclear, but
163 may be related to differences in BC chemistry or amounts applied as these vary from
164 study to study (e.g. Kim et al., 2017).

165   The significant interaction between the AVG and IR treatments is more difficult to
166 reconcile. The IR treatment was intended to significantly increase soil moisture content
167 compared to the no IR treatment, reducing water stress and likely *in planta* ethylene
168 production. It was noted that increased soil moisture content can directly influence
169 methanotrophic activity, as water-driven increases in microbial activity can enhance
170 methanotroph, whereas water content that exceed field capacity can rapidly decrease
171 CH_4 oxidation rates by reducing gas mobility through soil pores (Le Mer and Roger.,
172 2001). Given the initial soil water content and scale of the increase with the IR treatment,
173 direct stimulation of CH_4 oxidation was considered the most likely outcome when
174 considering plant-independent effects. Consequently, it was anticipated that any effect
175 of AVG on CH_4 oxidation (putatively via reductions in ethylene production) would only
176 manifest without IR, as the IR treatment would make the AVG treatment redundant.
177 However, CH_4 oxidation rates in plots treated with the either IR or IR and AVG in
178 combination were not significantly greater than untreated control plots. It is possible

179   that the moisture addition associated with the IR treatment was insufficient to

180   substantially alleviate plant drought stress, driving an increase in ethylene production,

181   which could then account for the numerical difference between the AVG and IR

182   treatments (Fig. 2). The water addition may have also been insufficient to meaningfully

183   directly stimulate methanotroph activity. However, it would be expected that the

184   combination of IR and AVG would produce CH_4 oxidation rates either the same, or

185   potentially greater than, those observed for AVG alone. This was not the case, and the

186   explanation for the significant interaction remains unknown. As discussed above, it is

187   possible for increased soil moisture content to inhibit CH_4 oxidation via decreased

188   porosity and gas diffusion (see Zhou et al., 2014), but given the IR treatment alone did

189   not reduce CH_4 oxidation rates relative to the control, this is not a feasible explanation

190   in this case.

191   The lack of data explicitly describing ethylene release into soil in response to the

192   treatments is a limitation to this trial. However, the quantification of ethylene in soil is

193   not trivial, particularly when conducted over time (i.e. continuous) and was outside the

194   resources available for this study. However, given the findings of this study, and

195   considering treatments were field-based, further investigations of the interactions

196   between AVG, plant stress, and CH_4 oxidation should be conducted. In these studies,

197   consideration should be given to collection and integration of ethylene data, particularly

198   given that this data may help shed light on the nature of any interactions between

199   treatments.

200   Overall, the findings of this study indicate that application of an ethylene

201   biosynthesis inhibitor to plant tissue can cause a measurable increase in the capability

202   of soil to oxidise CH_4 under moisture stressed conditions. This supports the hypothesis

203   that the stress-induced production of ethylene by plants can disrupt the activity of

204   methanotrophs, as well as identifying a potential management pathway to help retain,

205   or even enhance, the methanotrophic capability of soils in productive systems. Given

206   the global importance of a positive feedback between environmental stress, plant

207   ethylene production, and lowered microbial CH_4 oxidation activity, further work in this

208   area is needed. In addition, methods to moderate impacts on the methanotrophic

community, such as use of alternative forms or rates of biochar application, require investigation to enable provision of important ecosystem services.

Fig. 1. Conceptual outline of the proposed relationships between soil CH$_4$ oxidation rates and aboveground plant biomass with regard to the anticipated effects of the treatments applied in this study. a) Under environmental stress, *in planta* ethylene production is stimulated, resulting in ethylene exudation into the soil atmosphere and the inhibition of soil CH$_4$ oxidation by methanotrophs. b) The application of irrigation (IR) increases soil moisture while the application of biochar (BC) increases soil moisture holding capacity, both acting to reduce plant stress and prevent ethylene exudation into the soil atmosphere. c) The application of AVG disrupts ethylene production, and limiting or preventing the inhibition of CH$_4$ oxidation by the stressed plant.
