16 **Abstract**

17 CO₂ outgassing from rivers is a critical component for evaluating riverine carbon
18 cycle, but it is poorly quantified largely due to limited measurements and modeling of
19 gas transfer velocity in subtropical streams and rivers. We measured CO₂ flux rates,
20 and calculated k and partial pressure ($p\text{CO}_2$) in 60 river networks of the Three Gorges
21 Reservoir (TGR) region, a typical area in the upper Yangtze River with monsoonal
22 climate and mountainous terrain. The determined k_{600} (gas transfer velocity
23 normalized to a Schmidt number of 600 (k_{600}) at a temperature of 20 °C) values
24 (48.4 ± 53.2 cm/h) showed large variability due to spatial variations in physical
25 controls on surface water turbulence. Our flux-derived k values using chambers were
26 comparable with model derived from flow velocities based on a subset of data. Unlike
27 in open waters, e.g. lakes, k_{600} is more pertinent to flow velocity and water depth in
28 the studied river systems. Our results show that TGR river networks emitted approx.
29 0.7 Tg CO₂ during monsoonal period using varying approaches such as chambers,
30 derived k_{600} values and developed k_{600} model. This study suggests that incorporating
31 scale-appropriate k measurements into extensive $p\text{CO}_2$ investigation is required to
32 refine basin-wide carbon budgets in the subtropical streams and small rivers. We
33 concluded that simple parameterization of k_{600} as a function of morphological
34 characteristics was site specific for regions / watersheds and hence highly variable in
35 rivers of the upper Yangtze. K_{600} models should be developed for stream studies to
36 evaluate the contribution of these regions to atmospheric CO₂.

37

40 1. Introduction

41 Rivers serve as a significant contributor of CO₂ to the atmosphere (Raymond et
42 al., 2013; Cole et al., 2007; Li et al., 2012; Tranvik et al., 2009). As a consequence,
43 accurate quantification of riverine CO₂ emissions is a key component to estimate net
44 continental carbon (C) flux (Raymond et al., 2013). More detailed observational data
45 and accurate measurement techniques are critical to refine the riverine C budgets (Li
46 and Bush, 2015; Raymond and Cole, 2001). Generally two methods are used to
47 estimate CO₂ areal fluxes from the river system, such as direct measurements floating
48 chambers (FCs), and indirect calculation of thin boundary layer (TBL) model that
49 depends on gas concentration at air-water gradient and gas transfer velocity, k (Guerin
50 et al., 2007; Xiao et al., 2014). Direct measurements are normally laborious, while the
51 latter method shows ease and simplicity and thus is preferred (Butman and Raymond,
52 2011; Lauerwald et al., 2015; Li et al., 2013; Li et al., 2012; Ran et al., 2015).

53 The areal flux of CO₂ (F , unit in mmol/m²/d) *via* the water–air interface by TBL
54 is described as follows:

$$55 F = k \times K_h \times \Delta pCO_2 \quad (1)$$

$$56 K_h = 10^{-(1.11 + 0.016 * T - 0.00007 * T^2)} \quad (2)$$

57 where k (unit in m/d) is the gas transfer velocity of CO₂ (also referred to as piston
58 velocity) at the *in situ* temperature (Li et al., 2016). ΔpCO_2 (unit in μ atm) is the
59 air-water gradient of pCO_2 (Borges et al., 2004). K_h (mmol/m³/ μ atm) is the
60 aqueous-phase solubility coefficient of CO₂ corrected using *in situ* temperature (T
61 in °C) (Li et al., 2016).

62 $\Delta p\text{CO}_2$ can be measured well in various aquatic systems, however, the accuracy
63 of the estimation of flux is depended on the k value. Broad ranges of k for CO_2
64 (Raymond and Cole, 2001; Raymond et al., 2012; Borges et al., 2004) were reported
65 due to variations in techniques, tracers used and governing processes. k is controlled
66 by turbulence at the surface aqueous boundary layer, hence, k_{600} (the standardized gas
67 transfer velocity at a temperature of 20 °C is valid for freshwaters) is parameterized as
68 a function of wind speed in open water systems of reservoirs, lakes, and oceans
69 (Borges et al., 2004; Guerin et al., 2007; Wanninkhof et al., 2009). While in streams
70 and small rivers, turbulence at the water-air interface is generated by shear stresses at
71 streambed, thus k is modeled using channel slope, water depth, and water velocity in
72 particular (Raymond et al., 2012; Alin et al., 2011). Variable formulations of k have
73 been established by numerous theoretical, laboratory and field studies, nonetheless,
74 better constraint on k levels is still required as its levels are very significant and
75 specific due to large heterogeneity in hydrodynamics and physical characteristics of
76 river networks. This highlights the importance of k measurements in a wide range of
77 environments for the accurate upscaling of CO_2 evasion, and for parameterizing the
78 physical controls on k_{600} . However, only few studies provide information of k for
79 riverine CO_2 flux in Asia (Alin et al., 2011; Ran et al., 2015), and those studies do not
80 address the variability of k in China's small rivers and streams.

81 Limited studies demonstrated that higher levels of k in the Chinese large rivers
82 (Liu et al., 2017; Ran et al., 2017; Ran et al., 2015; Alin et al., 2011), which contributed
83 to much higher CO_2 areal flux particularly in China's monsoonal rivers that are

84 impacted by hydrological seasonality. The monsoonal flow pattern and thus flow
85 velocity is expected to be different than other rivers in the world, as a consequence, k
86 levels should be different than others, and potentially is higher in subtropical
87 monsoonal rivers.

88 Considerable efforts, such as purposeful (Crusius and Wanninkhof,
89 2003; Jean-Baptiste and Poisson, 2000) and natural tracers (Wanninkhof, 1992) and
90 FCs (Alin et al., 2011; Borges et al., 2004; Prytherch et al., 2017; Guerin et al., 2007),
91 have been carried out to estimate accurate k values. The direct determination of k by
92 FCs is more popular due to simplicity of the technique for short-term CO₂ flux
93 measurements (Prytherch et al., 2017; Raymond and Cole, 2001; Xiao et al., 2014).
94 Prior reports, however, have demonstrated that k values and the parameterization of k
95 as a function of wind and/or flow velocity (probably water depth) vary widely across
96 rivers and streams (Raymond and Cole, 2001; Raymond et al., 2012). To contribute to
97 this debate, extensive investigation was firstly accomplished for determination of k in
98 rivers and streams of the upper Yangtze using FC method. Models of k were further
99 developed using hydraulic properties (i.e., flow velocity, water depth) by flux
100 measurements with chambers and TBL model. Our recent study preliminarily
101 investigated *p*CO₂ and air – water CO₂ areal flux as well as their controls from fluvial
102 networks in the Three Gorges Reservoir (TGR) area (Li et al., 2018). The past study
103 was based on two field works, and the diffusive models from other rivers / regions
104 were used. In this study, we attempted to derive k levels and develop the gas transfer
105 model in this area (mountainous streams and small rivers) for more accurate

106 quantification of CO₂ areal flux, and also to serve for the fluvial networks in the
107 Yangtze River or others with similar hydrology and geomorphology. Moreover, we
108 did detailed field campaigns in the two contrasting rivers Daning and Qijiang for
109 models (Fig. 1), the rest were TGR streams and small rivers (abbreviation in TGR
110 rivers). The study thus clearly stated distinct differences than the previous study (Li et
111 al., 2018) by the new contributions of specific objectives and data supplements, as
112 well as wider significance. Our new contributions to the literature thus include (1)
113 determination and controls of k levels for small rivers and streams in subtropical areas
114 of China, and (2) new models developed in the subtropical mountainous river
115 networks. The outcome of this study is expected to help in accurate estimation of CO₂
116 evasion from subtropical rivers and streams, and thus refine riverine C budget over a
117 regional/basin scale.

118

119 **2. Materials and methods**

120 **2.1. Study areas**

121 All field measurements were carried out in the rivers and streams of the Three
122 Gorges Reservoir (TGR) region (28°44'–31°40'N, 106°10'–111°10'E) that is locating
123 in the upper Yangtze River, China (Fig. 1). This region is subject to humid subtropical
124 monsoon climate with an average annual temperature ranging between 15 and 19 °C.
125 Average annual precipitation is approx. 1250 mm with large intra- and inter-annual
126 variability. About 75% of the annual total rainfall is concentrated between April and
127 September (Li et al., 2018).

128 The river sub-catchments include large scale river networks covering the
129 majority of the tributaries of the Yangtze in the TGR region, i.e., data of 48 tributaries
130 were collected. These tributaries have drainage areas that vary widely from 100 to
131 4400 km² with width ranging from 1 m to less than 100 m. The annual discharges
132 from these tributaries have a broad spectrum of 1.8 – 112 m³/s. Detailed samplings
133 were conducted in the two largest rivers of Daning (35 sampling sites) and Qijiang
134 (32 sites) in the TGR region. These two river basins drain catchment areas of 4200
135 and 4400 km². The studied river systems had width < 100 m, we thus defined them as
136 small rivers and streams. The Daning and Qijiang river systems are underlain by
137 widely carbonate rock, and locating in a typical karst area. The location of sampling
138 sites is deciphered in Fig. 1. The detailed information on sampling sites and primary
139 data are presented in the Supplement Materials (Appendix Table A1). The sampling
140 sites are outside the Reservoirs and are not affected by dam operation.

141

142 **2.2. Water sampling and analyses**

143 Three fieldwork campaigns from the main river networks in the TGR region
144 were undertaken during May through August in 2016 (i.e., 18-22 May for Daning, 21
145 June-2 July for the entire tributaries of TGR, and 15-18 August for Qijiang). A total
146 of 115 discrete grab samples were collected (each sample consisted of three
147 replicates). Running waters were taken using pre acid-washed 5-L high density
148 polyethylene (HDPE) plastic containers from depths of 10 cm below surface. The
149 samples were filtered through pre-baked Whatman GF/F (0.7- μ m pore size) filters on

150 the sampling day and immediately stored in acid-washed HDPE bottles. The bottles
151 were transported in ice box to the laboratory and stored at 4 °C for analysis.
152 Concentrations of dissolved organic carbon (DOC) were determined within 7 days of
153 water collection (Mao et al., 2017).

154 Water temperature (T), pH, DO saturation (DO%) and electrical conductivity
155 (EC) were measured *in situ* by the calibrated multi-parameter sondes (HQ40d HACH,
156 USA, and YSI 6600, YSI incorporated, USA). pH, the key parameter for $p\text{CO}_2$
157 calculation, was measured to a precision of ± 0.01 , and pH sonde was calibrated by
158 the certified reference materials (CRMs) before measurements with an accuracy of
159 better than $\pm 0.2\%$. Atmospheric CO_2 concentrations were determined *in situ* using
160 EGM-4 (Environmental Gas Monitor; PP SYSTEMS Corporation, USA). Total
161 alkalinity was measured using a fixed endpoint titration method with 0.0200 mol/L
162 hydrochloric acid (HCl) on the sampling day. DOC concentration was measured using
163 a total organic carbon analyzer (TOC-5000, Shimadzu, Japan) with a precision better
164 than 3% (Mao et al., 2017). All the used solvents and reagents in experiments were of
165 analytical-reagent grade.

166 Concomitant stream width, depth and flow velocity were determined along the
167 cross section, and flow velocity was determined using a portable flow meter LS300-A
168 (China), the meter shows an error of $<1.5\%$. Wind speed at 1 m over the water surface
169 (U_1) and air temperature (T_a) were measured with a Testo 410-1 handheld
170 anemometer (Germany). Wind speed at 10 m height (U_{10} , unit in m/s) was calculated
171 using the following formula (Crusius and Wanninkhof, 2003):

172
$$U_{10} = U_Z \left[1 + \frac{(C_{d10})^{1/2}}{K} \times \ln\left(\frac{10}{z}\right) \right] \quad (3)$$

173 where C_{d10} is the drag coefficient at 10 m height (0.0013 m/s), and K is the von
174 Karman constant (0.41), and z is the height (m) of wind speed measurement.

175 $U_{10}=1.208 \times U_1$ as we measured the wind speed at a height of 1m (U_1).

176 Aqueous pCO_2 was computed from the measurements of pH, total alkalinity, and
177 water temperature using CO₂ System (k_1 and k_2 are from Millero, 1979) (Lewis et al.,
178 1998). This program can yield high quality data (Li et al., 2013;Li et al., 2012;Borges
179 et al., 2004).

180

181 **2.3. Water-to-air CO₂ fluxes using FC method**

182 FCs (30 cm in diameter, 30 cm in height) were deployed to measure air-water
183 CO₂ fluxes and transfer velocities. They were made of cylindrical polyvinyl chloride
184 (PVC) pipe with a volume of 21.20 L and a surface area of 0.071 m². These
185 non-transparent, thermally insulated vertical tubes, covered by aluminum foil, were
186 connected *via* CO₂ impermeable rubber-polymer tubing (with outer and inner
187 diameters of 0.5 cm and 0.35 cm, respectively) to a portable non-dispersive infrared
188 CO₂ analyzer EGM-4 (PPSystems). Air was circulated through the EGM-4 instrument
189 *via* an air filter using an integral pump at a flow rate of 350 ml/min. The chamber
190 method was widely used and more details of advantages and limits on chambers were
191 reviewed elsewhere (Alin et al., 2011;Borges et al., 2004;Xiao et al., 2014).

192 Chamber measurements were conducted by deploying two replicate chambers or

193 one chamber for two times at each site. In sampling sites with low and favorable flow
194 conditions (Fig. S1), freely drifting chambers (DCs) were executed, while sampling
195 sites in rivers and streams with higher flow velocity were conducted with anchored
196 chambers (ACs) (Ran et al., 2017). DCs were used in sampling sites with current
197 velocity of < 0.1 m/s, this resulted in limited sites (a total of 6 sites) using DCs. ACs
198 would create overestimation of CO₂ emissions by a factor of several - fold (i.e., > 2)
199 in our studied region (Lorke et al., 2015). Data were logged automatically and
200 continuously at 1-min interval over a given span of time (normally 5-10 minutes) after
201 enclosure. The CO₂ area flux (mg/m²/h) was calculated using the following formula.

$$202 \quad F = 60 \times \frac{dp_{CO_2} \times M \times P \times T_0}{dt \times V_0 \times P_0 \times T} H \quad (4)$$

203 Where dp_{CO_2}/dt is the rate of concentration change in FCs ($\mu\text{l/l}/\text{min}$); M is the
204 molar mass of CO₂ (g/mol); P is the atmosphere pressure of the sampling site (Pa); T
205 is the chamber absolute temperature of the sampling time (K); V₀ is the molar volume
206 (22.4 l/mol), P₀ is atmosphere pressure (101325 Pa), and T₀ is absolute temperature
207 (273.15 K) under the standard condition; H is the chamber height above the water
208 surface (m) (Alin et al., 2011). We accepted the flux data that had a good linear
209 regression of flux against time ($R^2 \geq 0.95$, $p < 0.01$) following manufacturer's
210 specification. In our sampling points, all measured fluxes were retained since the
211 floating chambers yielded linearly increasing CO₂ against time.

212 Water samples from a total of 115 sites were collected. Floating chambers with
213 replicates were deployed in 101 sites (32 sampling sites in Daning, 37 sites in TGR
214 river networks and 32 sites in Qijiang). The sampling period covered spring and

215 summer season, our sampling points are reasonable considering a water area of 433
216 km². For example, 16 sites were collected for Yangtze system to examine
217 hydrological and geomorphological controls on $p\text{CO}_2$ (Liu et al., 2017), and 17 sites
218 for dynamic biogeochemical controls on riverine $p\text{CO}_2$ in the Yangtze basin (Liu et al.,
219 2016). Similar to other studies, sampling and flux measurements in the day would
220 tend to underestimate CO_2 evasion rate (Bodmer et al., 2016).

221

222 **2.4. Calculations of the gas transfer velocity**

223 The k was calculated by reorganizing Eq (1). To make comparisons, k is
224 normalized to a Schmidt (S_{CT}) number of 600 (k_{600}) at a temperature of 20 °C.

$$225 \quad k_{600} = k_T \left(\frac{600}{S_{CT}} \right)^{-0.5} \quad (5)$$

$$226 \quad S_{CT} = 1911.1 - 118.11T + 3.4527T^2 - 0.04132T^3 \quad (5)$$

227 Where k_T is the measured values at the *in situ* temperature (T , unit in °C), S_{CT} is the
228 Schmidt number of temperature T . Dependency of -0.5 was employed here as
229 measurement were made in turbulent rivers and streams in this study (Alin et al.,
230 2011; Borges et al., 2004; Wanninkhof, 1992).

231

232 **2.5. Estimation of river water area**

233 Water surface is an important parameter for CO_2 efflux estimation, while it
234 depends on its climate, channel geometry and topography. River water area therefore
235 largely fluctuates with much higher areal extent of water surface particularly in
236 monsoonal season. However, most studies do not consider this change, and a fraction

237 of the drainage area is used in river water area calculation (Zhang et al., 2017). In our
238 study, a 90 m resolution SRTM DEM (Shuttle Radar Topography Mission digital
239 elevation model) data and Landsat images in dry season were used to delineate river
240 network, and thus water area (Zhang et al., 2018), whilst, stream orders were not
241 extracted. Water area of river systems is generally much higher in monsoonal season
242 in comparison to dry season, for instance, Yellow River showed 1.4-fold higher water
243 area in the wet season than in the dry season (Ran et al., 2015). Available dry-season
244 image was likely to underestimate CO₂ estimation.

245

246 **2.6. Data processing**

247 Prior to statistical analysis, we excluded k_{600} data for samples with the air-water
248 $p\text{CO}_2$ gradient $<110 \mu\text{atm}$, since the error in the k_{600} calculations drastically enhances
249 when $\Delta p\text{CO}_2$ approaches zero (Borges et al., 2004; Alin et al., 2011), and datasets with
250 $\Delta p\text{CO}_2 >110 \mu\text{atm}$ provide an error of $<10\%$ on k_{600} computation. Thus, we discarded
251 the samples (36.7% of sampling points with flux measurements) with $\Delta p\text{CO}_2 <110$
252 μatm for k_{600} model development, while for the flux estimations from diffusive TBL
253 model and floating chambers, all samples were included.

254 Spatial differences (Daning, Qijiang and entire tributaries of TGR region) were
255 tested using the nonparametric Mann Whitney U-test. Multivariate statistics, such as
256 correlation and stepwise multiple linear regression, were performed for the models of
257 k_{600} using potential physical parameters of wind speed, water depth, and current
258 velocity as the independent variables (Alin et al., 2011). Data analyses were

259 conducted from both separated data and combined data of river systems. k models
260 were obtained by water depth using data from the TGR rivers, while by flow velocity
261 in the Qijiang, whilst, models were not developed for Daning and combined data. All
262 statistical relationships were significant at $p < 0.05$. The statistical processes were
263 conducted using SigmaPlot 11.0 and SPSS 16.0 for Windows (Li et al., 2009; Li et al.,
264 2016).

265

266 **3. Results**

267 **3.1. CO₂ partial pressure and key water quality variables**

268 The significant spatial variations in water temperature, pH, $p\text{CO}_2$ and DOC were
269 observed among Daning, TGR and Qijiang rivers whereas alkalinity did not display
270 such variability (Fig. S2). pH varied from 7.47 to 8.76 with exceptions of two quite
271 high values of 9.38 and 8.87 (total mean: 8.39 ± 0.29). Significantly lower pH was
272 observed in TGR rivers (8.21 ± 0.33) (Table 1; $p < 0.001$; Fig. S2). $p\text{CO}_2$ varied
273 between 50 and 4830 μatm with mean of $846 \pm 819 \mu\text{atm}$ (Table 1). There were 28.7%
274 of samples that had $p\text{CO}_2$ levels lower than 410 μatm , while the studied rivers were
275 overall supersaturated with reference to atmospheric CO₂ and act as a source for the
276 atmospheric CO₂. The $p\text{CO}_2$ levels were 2.1 to 2.6-fold higher in TGR rivers than
277 Daning ($483 \pm 294 \mu\text{atm}$) and Qijiang Rivers ($614 \pm 316 \mu\text{atm}$) (Fig. S2).

278 There was significantly higher concentration of DOC in the TGR rivers ($12.83 \pm$
279 7.16 mg/l) than Daning and Qijiang Rivers (3.76 ± 5.79 vs $1.07 \pm 0.33 \text{ mg/l}$ in Qijiang
280 and Daning) ($p < 0.001$; Fig. S3). Moreover, Qijiang showed significantly higher

281 concentration of DOC than Daning (3.76 ± 5.79 vs 1.07 ± 0.33 mg/l in Qijiang and
282 Daning) ($p < 0.001$ by Mann-Whitney Rank Sum Test; Fig. S3).

283 **3.2. CO₂ flux using floating chambers**

284 The calculated CO₂ areal fluxes were higher in TGR rivers (217.7 ± 334.7
285 mmol/m²/d, $n = 35$), followed by Daning (122.0 ± 239.4 mmol/m²/d, $n = 28$) and
286 Qijiang rivers (50.3 ± 177.2 mmol/m²/d, $n = 32$) (Fig. 2). The higher CO₂ evasion
287 from the TGR rivers is consistent with high riverine $p\text{CO}_2$ levels. The mean CO₂
288 emission rate was 133.1 ± 269.1 mmol/m²/d ($n = 95$) in all three rivers sampled. The
289 mean CO₂ flux differed significantly between TGR rivers and Qijiang (Fig. 2).

290

291 **3.3. k levels**

292 A total of 64 data were used (10 for Daning River, 33 for TGR rivers and 21 for
293 Qijiang River) to develop k model after removal of samples with $\Delta p\text{CO}_2$ less than 110
294 μatm (Table 2). No significant variability in k_{600} values were observed among the
295 three rivers sampled (Fig. 3). The mean k_{600} (unit in cm/h) was relatively higher in
296 Qijiang (60.2 ± 78.9), followed by Daning (50.2 ± 20.1) and TGR rivers (40.4 ± 37.6),
297 while the median k_{600} (unit in cm/h) was higher in Daning (50.5), followed by TGR
298 rivers (30.0) and Qijiang (25.8) (Fig. 3; Table S1). Combined k_{600} data were averaged
299 to 48.4 ± 53.2 cm/h (95% CI: 35.1-61.7), and it is 1.5-fold higher than the median
300 value (32.2 cm/h) (Fig. 3).

301 Contrary to our expectations, no significant relationship was observed between
302 k_{600} and water depth, and current velocity using the entire data in the three river

303 systems (TGR streams and small rivers, Danning and Qjiang) (Fig. S4). There were
304 not statistically significant relationships between k_{600} and wind speed using separated
305 data or combined data. Flow velocity showed slightly linear relation with k_{600} , and the
306 extremely high value of k_{600} was observed during the periods of higher flow velocity
307 (Fig. S4a) using combined data. Similar trend was also observed between water depth
308 and k_{600} values (Fig. S4b). k_{600} as a function of water depth was obtained in the TGR
309 rivers, but it explained only 30% of the variance in k_{600} . However, model using data
310 from Qjiang could explain 68% of the variance in k_{600} (Fig. 4b), and it was in line
311 with general theory.

312

313 **4. Discussion**

314 **4.1. Uncertainty assessment of $p\text{CO}_2$ and flux-derived k_{600} values**

315 The uncertainty of flux-derived k values mainly stem from $\Delta p\text{CO}_2$ (unit in ppm)
316 and flux measurements (Bodmer et al., 2016; Golub et al., 2017; Lorke et al., 2015).
317 Thus we provided uncertainty assessments caused by dominant sources of uncertainty
318 from measurements of aquatic $p\text{CO}_2$ and CO_2 areal flux since uncertainty of
319 atmospheric CO_2 measurement could be neglected.

320 In our study, aquatic $p\text{CO}_2$ was computed based on pH, alkalinity and water
321 temperature rather than directly measured. Recent studies highlighted $p\text{CO}_2$
322 uncertainty caused by systematic errors over empiric random errors (Golub et al.,
323 2017). Systematic errors are mainly attributed to instrument limitations, i.e., sondes of
324 pH and water temperature. The relative accuracy of temperature meters was ± 0.1 °C

325 according to manufacturers' specifications, thus the uncertainty of water T propagated
326 on uncertainty in $p\text{CO}_2$ was minor (Golub et al., 2017). Systematic errors therefore
327 stem from pH, which has been proved to be a key parameter for biased $p\text{CO}_2$
328 estimation calculated from aquatic carbon system (Li et al., 2013; Abril et al., 2015).
329 We used a high accuracy of pH electrode and the pH meters were carefully calibrated
330 using CRMs, and *in situ* measurements showed an uncertainty of ± 0.01 . We then run
331 an uncertainty of ± 0.01 pH to quantify the $p\text{CO}_2$ uncertainty, and an uncertainty of $\pm 3\%$
332 was observed. Systematic errors thus seemed to show little effects on $p\text{CO}_2$ errors in
333 our study.

334 Random errors are from repeatability of carbonate measurements. Two replicates
335 for each sample showed the uncertainty of within $\pm 5\%$, indicating that uncertainty in
336 $p\text{CO}_2$ calculation from alkalinity measurements could be minor.

337 The measured pH ranges also exhibited great effects on $p\text{CO}_2$ uncertainty (Hunt
338 et al., 2011; Abril et al., 2015). At low pH, $p\text{CO}_2$ can be overestimated when
339 calculated from pH and alkalinity (Abril et al., 2015). Samples for CO_2 fluxes
340 estimated from pH and alkalinity showed pH average of 8.39 ± 0.29 (median 8.46 with
341 quartiles of 8.24-8.56) ($n=115$). Thus, overestimation of calculated CO_2 areal flux
342 from pH and alkalinity is likely to be minor. Further, contribution of organic matter to
343 non-carbonate alkalinity is likely to be neglected because of low DOC (mean 6.67
344 mg/L; median 2.51 mg/L) (Hunt et al., 2011; Li et al., 2013).

345 Efforts have been devoted to measurement techniques (comparison of FC, eddy
346 covariance-EC and boundary layer model-BLM) for improving CO_2 quantification

347 from rivers because of a notable contribution of inland waters to the global C budget,
348 which could have a large effect on the magnitude of the terrestrial C sink. Whilst,
349 prior studies reported inconsistent trends of CO₂ area flux by these methods. For
350 instance, CO₂ areal flux from FC was much lower than EC (Podgrajsek et al., 2014),
351 while areal flux from FC was higher than both EC and BLM elsewhere (Erkkila et al.,
352 2018), however, Schilder et al (Schilder et al., 2013) demonstrated that areal flux from
353 BLM was 33-320% of in-situ FC measurements. Albeit unsatisfied errors of varied
354 techniques and additional perturbations from FC exist, FC method is currently a
355 simple and preferred measurement for CO₂ flux because that choosing a right k value
356 remains a major challenge and others require high workloads (Martinsen et al., 2018).

357 Recent study further reported fundamental differences in CO₂ emission rates
358 between ACs and freely DFs (Lorke et al., 2015), i.e., ACs biased the gas areal flux
359 higher by a factor of 2.0-5.5. However, some studies observed that ACs showed
360 reasonable agreement with other flux measurement techniques (Galfalk et al., 2013),
361 and this straightforward, inexpensive and relatively simple method AC was widely
362 used (Ran et al., 2017). Water-air interface CO₂ flux measurements were primarily
363 made using ACs in our studied streams and small rivers because of relatively high
364 current velocity; otherwise, floating chambers will travel far during the measurement
365 period. In addition, inflatable rings were used for sealing the chamber headspace and
366 submergence of ACs was minimal, therefore, our measurements were potentially
367 overestimated but reasonable. We could not test the overestimation of ACs in this
368 study, the modified FCs, i.e., DCs and integration of ACs and DCs, and multi-method

369 comparison study including FCs, ECs and BLM should be conducted for a reliable
370 chamber method.

371 Our model was from a subset of the data (i.e., Qijiang), while CO₂ flux from our
372 model was in good agreement with the fluxes from FC, determined k and other
373 models when the developed model was applied for the whole dataset (please refer to
374 Tables 2 and 3). The comparison of the fluxes from variable methods suggested that
375 the model can be used for riverine CO₂ flux at catchment scale or regional scale
376 though it cannot be used at individual site. Recent studies, however, did not test the
377 applicability of models when k₆₀₀ models from other regions were employed. Our k₆₀₀
378 values were close to the average of Ran et al. (2015) (measured with drifting
379 chambers) and Liu et al. (2017) (measured with static chambers in canoe shape), this
380 indicated that our potential overestimation was limited. However, since we had very
381 limited drifting chamber measurements because of high current velocity, the
382 relationships with chamber derived k₆₀₀ values and flow velocity/depth only with the
383 drifting chamber data could not be tested. Whereas, we acknowledged that k₆₀₀ could
384 be over-estimated using AFs.

385 The extremely high values (two values of 260 and 274 cm/h) are outside of the
386 global ranges and also considerably higher than k₆₀₀ values in Asian rivers.
387 Furthermore, the revised model was comparable to the published models (Fig. 4), i.e.,
388 models of Ran et al. (2015) (measured with drifting chambers) and Liu et al. (2017)
389 (measured with static chambers in canoe shape), which suggested that exclusion of
390 the two extremely values were reasonable and urgent, this was further supported by

391 the CO₂ flux using different approaches (Tables 2 and 3).

392 Sampling seasonality considerably regulated riverine *p*CO₂ and gas transfer
393 velocity and thus water-air interface CO₂ evasion rate (Ran et al., 2015; Li et al., 2012).
394 We sampled waters in wet season (monsoonal period) due to that it showed wider
395 range of flow velocity and thus it covered the *k*₆₀₀ levels in the whole hydrological
396 season. Wet season generally had higher current velocity and thus higher gas transfer
397 velocity (Ran et al., 2015), while aquatic *p*CO₂ was variable with seasonality. We
398 recently reported that riverine *p*CO₂ in the wet season was 81% the level in the dry
399 season (Li et al., 2018), and prior study on the Yellow River reported that *k* level in
400 the wet season was 1.8-fold higher than in the dry season (Ran et al., 2015), while
401 another study on the Wuding River demonstrated that *k* level in the wet season was
402 83%-130% of that in the dry season (Ran et al., 2017). Thus, we acknowledged a
403 certain amount of errors on the annual flux estimation from sampling campaigns
404 during the wet season in the TGR area, while this uncertainty could not be significant
405 because that the diluted *p*CO₂ could alleviate the overestimated emission by increased
406 *k* level in the wet season (stronger discussion please refer to SOM).

407

408 **4.2. Determined *k* values relative to world rivers**

409 We derived first-time the *k* values in the subtropical streams and small rivers.
410 Our determined *k*₆₀₀ levels with a 95% CI of 35.1 to 61.7 (mean: 48.4) cm/h is
411 compared well with a compilation of data for streams and small rivers (e.g., 3-70
412 cm/h) (Raymond et al., 2012). Our determined *k*₆₀₀ values are greater than the global

413 rivers' average (8 - 33 cm/h) (Raymond et al., 2013;Butman and Raymond, 2011), and
414 much higher than mean for tropical and temperate large rivers (5-31 cm/h) (Alin et al.,
415 2011). These studies evidences that k_{600} values are highly variable in streams and
416 small rivers (Alin et al., 2011;Ran et al., 2015). Though the mean k_{600} in the TGR,
417 Daning and Qijiang is higher than global mean, however, it is consistent with k_{600}
418 values in the main stream and river networks of the turbulent Yellow River (42 ± 17
419 cm/h) (Ran et al., 2015), and Yangtze (38 ± 40 cm/h) (Liu et al., 2017) (Table S2).

420 The calculated $p\text{CO}_2$ levels were within the published range, but towards the
421 lower-end of published concentrations compiled elsewhere (Cole and Caraco, 2001;Li
422 et al., 2013). The total mean $p\text{CO}_2$ (846 ± 819 μatm) in the TGR, Danning and Qijiang
423 sampled was one third lower of global river's average (3220 μatm) (Cole and Caraco,
424 2001). The lower $p\text{CO}_2$ than most of the world's river systems, particularly the
425 under-saturated values, demonstrated that heterotrophic respiration of terrestrially
426 derived DOC was not significant. Compared with high alkalinity, the limited delivery
427 of DOC particularly in the Daning and Qijiang river systems (Figs. S2 and S3) also
428 indicated that in-stream respiration was limited. These two river systems are
429 characterized by karst terrain and underlain by carbonate rock, where photosynthetic
430 uptake of dissolved CO_2 and carbonate minerals dissolution considerably regulated
431 aquatic $p\text{CO}_2$ (Zhang et al., 2017).

432 Higher pH levels were observed in Daning and Qijiang river systems ($p < 0.05$ by
433 Mann-Whitney Rank Sum Test), where more carbonate rock exists that are
434 characterized by karst terrain. Our pH range was comparable to the recent study on

435 the karst river in China (Zhang et al., 2017). Quite high values (8.39 ± 0.29 , ranging
436 between 7.47 and 9.38; 95% confidence interval: 8.33-8.44) could increase the
437 importance of the chemical enhancement, nonetheless, few studies did take chemical
438 enhancement into account (Wanninkhof and Knox, 1996; Alshboul and Lorke, 2015).
439 The chemical enhancement can increase the CO₂ areal flux by a factor of several folds
440 in lentic systems with low gas transfer velocity, whilst enhancement factor decreased
441 quickly as k_{600} increased (Alshboul and Lorke, 2015). Our studied rivers are located
442 in mountainous area with high k_{600} , which could cause minor chemical enhancement
443 factor. This chemical enhancement of CO₂ flux was also reported to be limited in
444 high-pH and also turbulent rivers (Zhang et al., 2017).

445

446 **4.3. Hydraulic controls of k_{600}**

447 It has been well established that k_{600} is governed by a multitude of physical
448 factors particularly current velocity, wind speed, stream slope and water depth, of
449 which, wind speed is the dominant factor of k in open waters such as large rivers and
450 estuaries (Alin et al., 2011; Borges et al., 2004; Crusius and Wanninkhof,
451 2003; Raymond and Cole, 2001). In contrast k_{600} in small rivers and streams is closely
452 linked to flow velocity, water depth and channel slope (Alin et al., 2011; Raymond et
453 al., 2012). Several studies reported that the combined contribution of flow velocity
454 and wind speed to k is significant in the large rivers (Beaulieu et al., 2012; Ran et al.,
455 2015). Thus, k_{600} values are higher in the Yellow River (ca. 0-120 cm/h) as compared
456 to the low-gradient River Mekong (0-60 cm/h) (Alin et al., 2011; Ran et al., 2015), due

457 to higher flow velocity in the Yellow River (1.8 m/s) than Mekong river (0.9 ± 0.4 m/s),
458 resulting in greater surface turbulence and higher k_{600} level in the Yellow (42 ± 17
459 cm/h) than Mekong river (15 ± 9 cm/h). This could substantiate the higher k_{600} levels
460 and spatial changes in k_{600} values of our three river systems. For instance, similar to
461 other turbulent rivers in China (Ran et al., 2017; Ran et al., 2015), high k_{600} values in
462 the TGR, Daning and Qjiang rivers were due to mountainous terrain catchment, high
463 current velocity (10 – 150 cm/s) (Fig. 4b), bottom roughness, and shallow water depth
464 (10 - 150 cm) (Fig. 4a). It has been suggested that shallow water enhances bottom
465 shear, and the resultant turbulence increases k values (Alin et al., 2011; Raymond et al.,
466 2012). These physical controls are highly variable across environmental types (Figs.
467 4a and 4b), hence, k values are expected to vary widely (Fig. 3). The k_{600} values in the
468 TGR rivers showed wider range (1-177 cm/h; Fig. 3; Table S1), spanning more than 2
469 orders of magnitude across the region, and it is consistent with the considerable
470 variability in the physical processes on water turbulence across environmental settings.
471 Similar broad range of k_{600} levels was also observed in the China's Yellow basin (ca.
472 0-123 cm/h) (Ran et al., 2015; Ran et al., 2017).

473 Absent relationships between riverine k_{600} and wind speed were consistent with
474 earlier studies (Alin et al., 2011; Raymond et al., 2012). The lack of strong correlation
475 between k_{600} and physical factors using the combined data were probably due to
476 combined effect of both flow velocity and water depth, as well as large diversity of
477 channel morphology, both across and within river networks in the entire catchment
478 (60, 000 km²). This is further collaborated by weak correlations between k_{600} and flow

479 velocity in the TGR rivers (Fig. 4), where one or two samples were taken for a large
480 scale examination. We provided new insights into k_{600} parameterized using current
481 velocity. Nonetheless, k_{600} from our flow velocity based model (Fig. 4b) was
482 potentially largely overestimated with consideration of other measurements (Alin et
483 al., 2015; Ran et al., 2015; Ran et al., 2017). When several extremely values were
484 removed, k_{600} (cm/h) was parameterized as follows ($k_{600} = 62.879FV + 6.8357$, $R^2 =$
485 0.52 , $p=0.019$, FV-flow velocity with a unit of m/s), and this revised model was in
486 good agreement with the model in the river networks of the Yellow River (Ran et al.,
487 2017), but much lower than the model developed in the Yangtze system (Liu et al.,
488 2017) (Fig. 4c). This was reasonable because of k_{600} values in the Yangtze system
489 were from large rivers with higher turbulence than Yellow and our studied rivers.
490 Furthermore, the determined k_{600} using FCs was, on average, consistent with the
491 revised model (Table 2). These differences in relationship between spatial changes in
492 k_{600} values and physical characteristics further corroborated heterogeneity of channel
493 geomorphology and hydraulic conditions across the investigated rivers.

494 The subtropical streams and small rivers are biologically more active and are
495 recognized to exert higher CO_2 areal flux to the atmosphere, however, their
496 contribution to riverine carbon cycling is still poorly quantified because of data
497 paucity and the absence of k in particular. Larger uncertainty of riverine CO_2 emission
498 in China was anticipated by use of k_{600} from other continents or climate zones. For
499 instance, k_{600} for CO_2 emission from tributaries in the Yellow River and karst rivers
500 was originated from the model in the Mekong (Zhang et al., 2017), and Pearl (Yao et

501 al., 2007), Longchuan (Li et al., 2012), and Metropolitan rivers (Wang et al., 2017),
502 which are mostly from temperate regions. Our k_{600} values will therefore largely
503 improve the estimation of CO₂ evasion from subtropical streams and small rivers, and
504 improve to refine riverine carbon budget. More studies, however, are clearly needed
505 to build the model, based on flow velocity and slope/water depth given the difficulty
506 in k quantification on a large scale.

507

508 **4.4. Implications for large scale estimation**

509 We compared CO₂ areal flux by FCs and models developed here (Fig. 4) and
510 other studies (Alin et al., 2011) (Tables 2 and 3). CO₂ evasion was estimated for rivers
511 in China with k values ranged between 8 and 15 cm/h (Li et al., 2012; Yao et al.,
512 2007; Wang et al., 2011) (Table S2). These estimates of CO₂ evasion rate were
513 considerably lower than using present k_{600} values (48.4 ± 53.2 cm/h). For instance,
514 CO₂ emission rates in the Longchuan River (e.g., $k = 8$ cm/h) and Pearl River
515 tributaries (e.g., $k = 8-15$ cm/h) were 3 to 6 times higher using present k values
516 compared to earlier estimates. We found that the determined k_{600} average was
517 marginally beyond the levels from water depth based model and the model developed
518 by Alin et al (Alin et al., 2011), while equivalent to the flow velocity based revised
519 model, resulting in similar patterns of CO₂ emission rates (Table 2). Hence selection
520 of k values would significantly hamper the accuracy of the flux estimation. Therefore
521 k must be estimated along with $p\text{CO}_2$ measurements to accurate flux estimations.

522 We used our measured CO₂ emission rates by FCs for upscaling flux estimates

523 during monsoonal period given the sampling in this period and it was found to be 0.70
524 Tg CO₂ for all rivers sampled in our study (Table 3a). The estimated emission in the
525 monsoonal period was close to that of the revised model (0.71 ± 0.66 (95%
526 confidence interval: 0.46 - 0.94) Tg CO₂), and using the determined k average, i.e.,
527 0.69 ± 0.65 (95% confidence interval: 0.45-0.93) Tg CO₂, but slightly higher than the
528 estimation using water-depth based model (0.54 ± 0.51 Tg CO₂) and Alin's model
529 (0.53 ± 0.50 Tg CO₂) (Table 3b). This comparable CO₂ flux further substantiated the
530 exclusion of extremely k₆₀₀ values for developing model (Fig. 4). The CO₂ evasion
531 comparison by variable approaches also implied that the original flow velocity based
532 model (two extremely k₆₀₀ values were included; Fig. 4b) largely over-estimated the
533 CO₂ fluxes, i.e., 1.66 ± 1.55 (1.08-2.23) Tg CO₂, was 2.3-3 fold higher than other
534 estimations (Table 3b), and our earlier evasion using TBL on the TGR river networks
535 (Li et al., 2018). Moreover, our estimated CO₂ emission in the monsoonal period also
536 suggests that CO₂ annual emissions from rivers and streams in this area were
537 previously underestimated, i.e., 0.03 Tg CO₂/y (Li et al., 2017) and 0.37-0.44 Tg
538 CO₂/y (Yang et al., 2013) as the former used TBL model with a lower k level, and the
539 latter employed floating chambers, but they both sampled very limited tributaries (i.e.,
540 2-3 rivers). Therefore, measurements of k must be made mandatory along with pCO₂
541 measurement in the river and stream studies.

542

543 **5. Conclusion**

544 We provided first determination of gas transfer velocity (k) in the subtropical

545 streams and small rivers in the upper Yangtze. High variability in k values (mean 48.4
546 ± 53.2 cm/h) was observed, reflecting the variability of morphological characteristics
547 on water turbulence both within and across river networks. We highlighted that k
548 estimate from empirical model should be pursued with caution and the significance of
549 incorporating k measurements along with extensive $p\text{CO}_2$ investigation is highly
550 essential for upscaling to watershed/regional scale carbon (C) budget.

551 Riverine $p\text{CO}_2$ and CO_2 areal flux showed pronounced spatial variability with
552 much higher levels in the TGR rivers. The CO_2 areal flux was averaged at $133.1 \pm$
553 269.1 mmol/m²/d using FCs, the resulting emission in the monsoonal period was
554 around 0.7 Tg CO_2 , similar to the scaling up emission with the determined k , and the
555 revised flow velocity based model, while marginally above the water depth based
556 model. More work is clearly needed to refine the k modeling in the river systems of
557 the upper Yangtze River for evaluating regional C budgets.

558

559 **Acknowledgements**

560 This study was funded by “the Hundred-Talent Program” of the Chinese Academy of
561 Sciences (R53A362Z10; granted to Dr. Li), and the National Natural Science
562 Foundation of China (Grant No. 31670473). We are grateful to Mrs. Maofei Ni and
563 Tianyang Li, and Miss Jing Zhang for their assistance in the field works. Users can
564 access the original data from an Appendix. Special thanks are given to editor David
565 Butman and anonymous reviewers for improving the Ms.

719

720 **Table 1.** Statistics of all the data from three river systems (separated statistics please
 721 refer to Figs. S2 and S3 in the Supplementary material).

		Water T (⁰ C)	pH	Alkalinity (μ eq/l)	p CO ₂ (μ atm)	DO%	DOC (mg/L)
Number		115	115	115	115	56	114
Mean		22.5	8.39	2589.1	846.4	91.5	6.67
Median		22.8	8.46	2560	588.4	88.8	2.51
Std. Deviation		6.3	0.29	640.7	818.5	8.7	7.62
Minimum		11.7	7.47	600	50.1	79.9	0.33
Maximum		34	9.38	4488	4830.4	115.9	37.48
Percentiles	25	16.3	8.24	2240	389.8	84.0	1.33
	75	29	8.56	2920	920.4	99.1	9.96
95% CI for Mean	Lower Bound	21.4	8.33	2470.8	695.2	89.1	5.26
	Upper Bound	23.7	8.44	2707.5	997.6	93.8	8.09

722

723 CI-Confidence Interval.

724 **Table 2.** Comparison of different model for CO₂ areal flux estimation using combined
 725 data (unit is mmol/m²/d for CO₂ areal flux and cm/h for k₆₀₀).
 726

		From FC	Flow velocity-based model (Fig. 4b) ^a	Water depth-based model (Fig.3a)	Alin's model
k ₆₀₀		48.4 ^b	116.5 ^c	38.3	37.6
CO ₂ areal flux					
Mean		198.1	476.7	156.6	154.0
S.D.		185.5	446.2	146.6	144.2
95% CI for Mean ^a	Lower Bound	129.5	311.5	102.3	100.6
	Upper Bound	266.8	641.8	210.8	207.4

727

728 CI-Confidence Interval

729 ^aFlow velocity –based model is from a subset of the data (please refer to Fig. 4)

730 ^bMean value determined using floating chambers (FC).

731 ^c-This figure is revised to be 49.6 cm/h if the model ($k_{600} = 62.879FV + 6.8357$, $R^2 =$
 732 0.52 , $p=0.019$) is used (the model is obtained by taking out two extremely values;
 733 please refer to Fig. 4c), and the corresponding CO₂ areal flux is 203 ± 190 mmol/m²/d.

734

735 **Table 3.** CO₂ emission during monsoonal period (May through Oct.) from total rivers
 736 sampled in the study.

737 (a) Upscaling using CO₂ areal flux (mean ± S.D.) by FC during monsoonal period.

	Catchment Area km ²	Water surface km ²	CO ₂ areal flux mmol/m ² /d	CO ₂ emission Tg CO ₂
Daning	4200	21.42	122.0 ± 239.4	0.021
Qijiang	4400	30.8	50.3 ± 177.2	0.0125
TGR river	50000	377.78	217.7 ± 334.7	0.666
Total				0.70

738

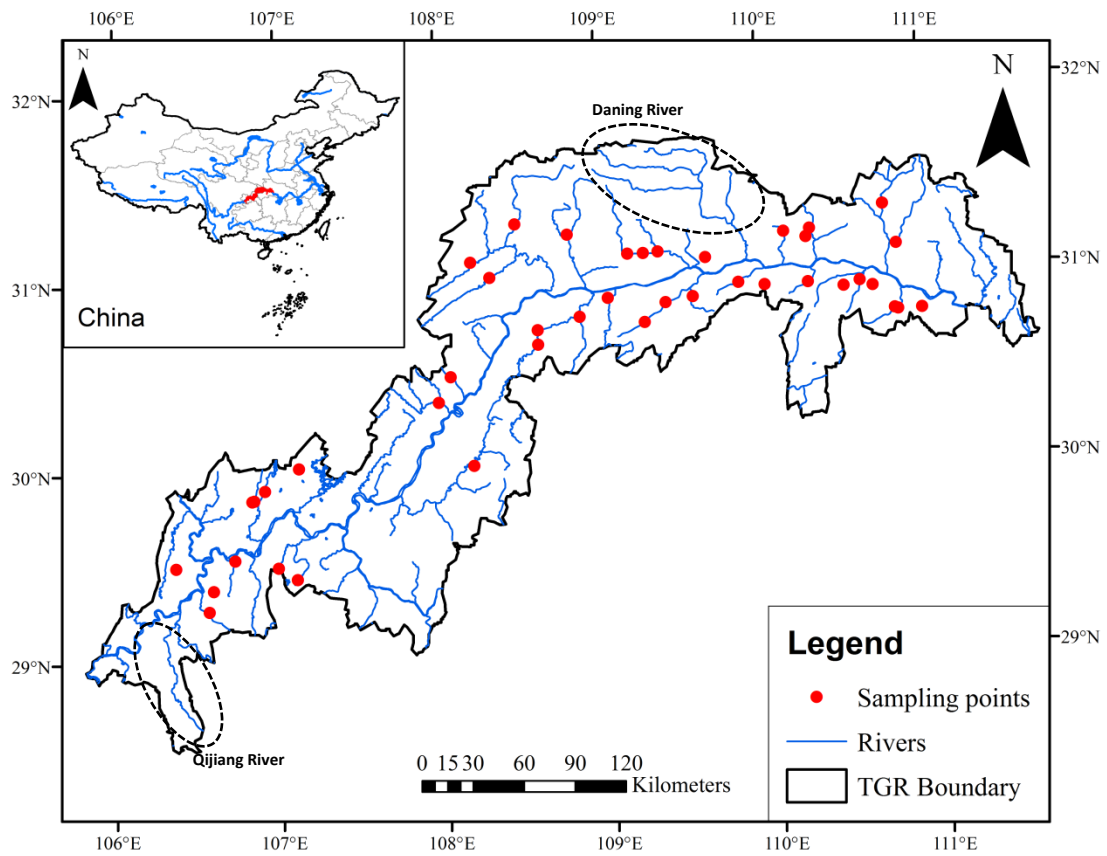

739 (b) Upscaling using determined k₆₀₀ average and models (whole dataset are used
 740 here).

	From determined k ₆₀₀ mean	Flow velocity-based model (Fig. 4b) (numbers in bracket is from the revised model; Fig. 4c)	Water depth-based model (Fig. 4a)	Alin's model
Mean	0.69	1.66 (0.71)	0.54	0.53
S.D.	0.65	1.55 (0.66)	0.51	0.50
95% CI for				
Lower Bound	0.45	1.08 (0.46)	0.36	0.35
Upper Bound	0.93	2.23 (0.94)	0.74	0.72

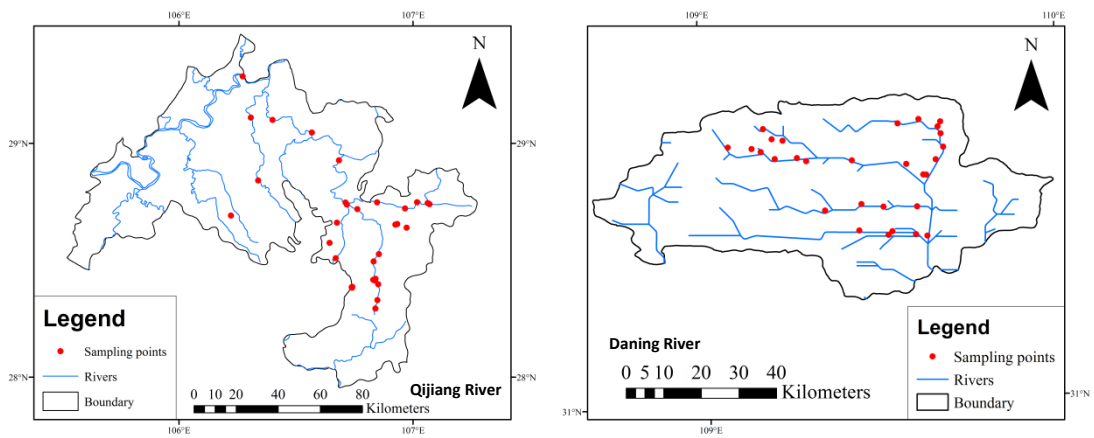

741 A total water area of approx. 430 km² for all tributaries (water area is from Landsat

742 ETM+ in 2015); CO₂ emission upscaling (Tg CO₂ during May through October) was

743 conducted during the monsoonal period because of the sampling in this period.

744

745

746 **Fig. 1.** Map of sampling locations of major rivers and streams in the Three Gorges
 747 Reservoir region, China.

748

749

750 **Fig. 2.** Boxplots of CO₂ emission rates by floating chambers in the investigated three
 751 river systems (different letters represent statistical differences at p<0.05 by
 752 Mann-Whitney Rank Sum Test). (the black and red lines, lower and upper edges, bars
 753 and dots in or outside the boxes demonstrate median and mean values, 25th and
 754 75th, 5th and 95th, and <5th and >95th percentiles of all data, respectively). (For
 755 interpretation of the references to color in this figure legend, the reader is referred
 756 to the web version of this article) (Total means combined data from three river
 757 systems).

758

759 **Fig. 3.** Boxplots of k_{600} levels in the investigated three river systems (there is not a
 760 statistically significant difference in k among sites by Mann-Whitney Rank Sum Test).
 761 (the black and red lines, lower and upper edges, bars and dots in or outside the
 762 boxes demonstrate median and mean values, 25th and 75th, 5th and 95th, and <5th
 763 and >95th percentiles of all data, respectively). (For interpretation of the references
 764 to color in this figure legend, the reader is referred to the web version of this article)
 765 (Total means combined data from three river systems).

769 **Fig. 4.** The k_{600} as a function of water depth (WD) using data from TGR rivers (a), flow
 770 velocity (FV) using data from Qijiang (b), and comparison of the developed model

771 with other models (c) (others without significant relationships between k and
772 physical factors are not shown). The solid lines show regression, the dashed lines
773 represent 95% confidence band, and the red dash-dotted line represents the model
774 developed by Alin et al (2011) (Extremely values of 260 and 274 cm/h are removed in
775 panel b, the revised model would be $k_{600} = 62.879FV + 6.8357$, $R^2 = 0.52$, $p=0.019$) (in
776 panel c, 1-the revised model, 2-model from Ran et al., 2017, 3-model from Ran et al.,
777 2015, 4-model from Alin et al., 2011, 5-model from Liu et al., 2017) (1- $k_{600} =$
778 $62.879FV + 6.8357$; 2- $k_{600} = 58.47FV+7.99$; 3- $k_{600} = 13.677\exp(1.1FV)$; 4- $k_{600} = 35 FV$
779 $+ 13.82$; 5- $k_{600} = 6.5FV^2 + 12.9FV+0.3$) (unit of k in models 1-4 is cm/h, and unit of
780 m/d for model 5 is transferred to cm/h).

781
