27 **Abstract**

28

29 In 2015, we have collected more than 60,000 scavenging amphipod specimens during two
30 expeditions to the Clarion-Clipperton fracture Zone (CCZ), in the Northeast (NE) Pacific and
31 to the DISturbance and re-COLONisation (DisCOL) Experimental Area (DEA), a simulated
32 mining impact disturbance proxy in the Peru basin, Southeast (SE) Pacific. Here, we compare
33 biodiversity patterns of the larger specimens (> 15 mm) within and between these two
34 oceanic basins. Eight scavenging amphipod species are shared between these two areas, thus
35 indicating connectivity. We further provide evidence that disturbance proxies seem to
36 negatively affect scavenging amphipod biodiversity, as illustrated by a reduced alpha
37 biodiversity in the DEA (Simpson Index (D) = 0.62), when compared to the CCZ (D = 0.73)
38 and particularly of the disturbance site in the DEA and the site geographically closest to it.
39 Community compositions of the two basins differs, as evidenced by a Non-Metric
40 Dimensional Scaling (NMDS) analysis of beta biodiversity. The NMDS also shows a further
41 separation of the disturbance site (D1) from its neighbouring, undisturbed reference areas
42 (D2, D3, D4 and D5) in the DEA. A single species, *Abyssorchomene gerulicorbis*
43 (Shulenberger & Barnard, 1976), dominates the DEA with 60% of all individuals.

55

56 **Introduction**

57

58 The abyssal deep sea (3000 - 6000 m) represents the largest ecosystem on the planet, with the
59 abyssal seafloor covering approximately 54% of the Earth's solid surface (Rex et al. 1993;
60 Gage & Tyler, 1991). Since it is one of the least investigated ecosystems, there are still
61 extensive gaps in our knowledge of deep-sea fauna (German et al. 2011). Marine research has
62 thus far focused on coastal areas, hydrothermal vents or chemosynthetic habitats, whereas
63 open-ocean abyssal plains have been less extensively investigated (Ramirez-Llodra et al.
64 2010). This is unsurprising given the challenges of sampling this remote environment, which
65 is impeded by several confounding factors. For example, deep-sea sampling is both
66 financially expensive and labour intensive, and furthermore, constrained by the challenge of
67 deploying equipment at low temperatures (0.01 - 4.0°C) and at high hydrostatic pressures
68 (Sweetman et al. 2017). Therefore, to date very little of the deep sea has been sampled, and
69 the oversampling in the North Atlantic basin has created a biased knowledge base (McClain
70 & Hardy, 2010). Consequently, and owing to the low availability of data on deep-sea
71 biodiversity, and with the inherent risk of under-sampling, it is difficult to estimate species
72 richness in the deep sea.

73

74 In the traditional view of the deep sea, the abyss was considered to be homogeneous and
75 many species were thought to have large biogeographical ranges, their dispersal aided by an
76 apparent lack of barriers (Sanders, 1968). This hypothesis was challenged by the discovery of
77 chemosynthetic habitats e.g. hydrothermal vents (Lonsdale, 1977), cold seeps (Paull et al.
78 1984), seasonal fluctuations in primary productivity (Billett et al. 1983) and erratic whale-
79 falls (Smith et al. 1989). All of this research has demonstrated that the deep sea is an
80 heterogeneous environment and is controlled by many factors, including: Particulate Organic
81 Carbon (POC) flux, water depth, flow regime, current circulation, seafloor topography (Laver
82 et al. 1985) and also historical factors e.g. the opening of ocean basins (i.e. rifting), sea-level
83 rise and fall, and periods of deep-sea anoxia (Smith et al. 2006). All of these can result in a
84 mosaic of different communities (Levin et al. 2001), many of which do not follow a
85 latitudinal gradient (Brandt et al. 2007).

86

87 It has also been established that dispersal ability of species on the one hand, and their actual
88 geographic and bathymetric distribution range on the other, are not always linked, and are
89 often dependent on habitat suitability, fragmentation, and ecological flexibility (Lester et al.

90 2007; Liow 2007). Therefore, although the deep-seafloor includes some of the largest
91 contiguous features on the planet, the populations of many deep-sea species are spatially
92 fragmented, and may become increasingly so with continued human disturbance (Hilario et
93 al. 2015).

94

95 In the last decade, there has been an bigger demand for exploitation of deep-sea resources e.g.
96 rare earth element (REE) extraction (such as those concentrated in manganese nodule
97 provinces) (Ramirez-Llodra et al. 2011). As a result, ecologists are increasingly asked to
98 assess the ecological risks of these mining activities and to provide sustainable solutions for
99 its mitigation, in order to prevent adverse changes to the deep-sea ecosystem (ISA, 2017).

100

101 Glover et al. (2001) showed that abyssal sediments can contain high biodiversity with more
102 than 100 species of meiofaunal invertebrates (e.g. nematodes, copepods) and protists (e.g.
103 foraminifers) found every square meter. In spite of this, our knowledge on the deep-sea
104 ecosystem structure and functioning is still limited, and there is a paucity of data on the
105 distribution, drivers and origins of deep-sea communities at global scales. **This is especially
106 true for deep-sea invertebrates, including Amphipoda (Barnard 1961; Thurston 1990).**

107

108 Although recent morphological and molecular studies have shed new light on the distribution
109 and habitat niches of certain benthopelagic amphipods (e.g. *Eurythenes*) (Havermans, 2016;
110 Narahara-Nakano et al. 2017), there is little published so far on how widespread other
111 amphipod species may be. This lack of information on species richness and ecological
112 uniqueness hampers the answering of crucial questions on recoverability of anthropogenic
113 impacts. Ultimately this impedes ecologists from providing advice on sustainable deep-sea
114 mining practices, thus, underpinning the need for this dedicated deep-sea ecosystem research.

115

116 Here, we present distribution patterns of scavenging deep-sea amphipod communities, with
117 the first comparisons of their biogeography and community structures in two oceanic basins.
118 These two basins are the research areas for simulating/studying the anthropogenic impacts of
119 deep-sea nodule mining.

120

121 We are investigating whether there are differences and similarities in the species
122 compositions of the two basins (e.g. richness, abundances), and further exploit a disturbance
123 experiment to compare the biodiversity of this mining impact proxy to the undisturbed

124 reference areas. We discuss the possible implications of our findings; aiming to use them to
125 formulate recommendations regarding the pending deep-sea mining of manganese nodule
126 activities in the NE Pacific ecosystem.

127 **Material and Methods**

128

129 *Study area*

130

131 We investigated the amphipod communities of two oceanic basins (Figure 1); (i) the Clarion-
132 Clipperton Fracture Zone (CCZ, six million km², 7000 km wide), an economically important
133 manganese nodule field in the NE Pacific, comprising several different contractor claim
134 areas, (who to date, have exploration licences only), and nine designated Areas of Particular
135 Ecological Interest (APEIs) as designated by the International Seabed Authority (ISA)
136 (Lodge et al, 2014) and (ii) the DISturbance and re-COLONisation (DisCOL) Experimental
137 Area (DEA, 11 km², 4 km wide), a mining disturbance proxy (also containing manganese
138 nodules) in the Peru Basin in the SE Pacific. In 1989, the DEA sediment bed was artificially
139 disturbed using a plough-harrow to create 78 track marks (Appendix 1) (Thiel, 1992).. These
140 are supposed to simulate the type of disruption which would be caused by a commercial
141 mining operation This baseline study was a new approach in deep-sea risk assessment and is
142 still ongoing today, providing us with crucial data from this long-term ecological experiment.

143

144

145

146

147

148

149

150 **Figure 1: Geographic locations of the two study areas, the Clarion-Clipperton fracture**
 151 **Zone (CCZ) (Northeast Pacific) and the DISTurbance and re-COLONisation (DisCOL)**
 152 **Experimental Area (DEA) (Peru Basin, Southeast Pacific).** There are nine Areas of
 153 Particular Ecological Interest (APEIs) in the CCZ region, which are illustrated by 400 x 400
 154 km² white boxes. Grey boxes indicate the various contractor claim areas in the CCZ. We
 155 deployed eight amphipod traps across the CCZ, which is 16,000 km² and 7000 km wide, and
 156 five in the DEA, which encompasses 11 km² with a width of 4 km.

157

158 *Sampling*

159

160 In 2015 (26 years after the first impact in the DEA in 1989), two research expeditions with
 161 the “RV Sonne” visited the CCZ (cruise SO239) and revisited the DEA (cruise SO242-1 &
 162 SO242-2), to assess if and how the deep-sea faunal communities had recovered within the
 163 DEA, and to attempt to quantify their recolonization potential.

164

165 Amphipod samples were taken from the CCZ and DEA using a free-fall lander (120 x 120 x
 166 120 cm), to which four plastic traps were attached (two 20 x 25 x 40 cm traps with four cm
 167 openings and two 25 x 40 x 60 cm traps with eight cm openings), baited for each station with
 168 an 800 g mixture of mackerel, squid and shrimp. Using this specially designed deep-sea
 169 sampling equipment, more than 60,000 specimens of scavenging amphipods were collected
 170 from the CCZ and the DEA sites.

171

172 The baited trap was deployed eight times across the CCZ at a depth range of 4116 - 4932 m
 173 (samples C1 - C8), and five times in the DEA at a depth range of 4078 - 4307 m (samples D1

174 - D5; Figure 1, Table 1). In the CCZ, we sampled within three different contractor claim
175 areas (Table 1) to obtain a pre-disturbance baseline, and to then compare it with one of the
176 nine protected APEIs around the CCZ. In contrast, in the DEA, sampling was conducted once
177 within the disturbed area (D1), twice 10 km away (D2, D3) and twice 40 km away (D4, D5)
178 from D1 in four surrounding reference areas (see Figure 1).

202 **Table 1: Station overview.**

203 Codes refer to the codes used in this paper in figures 1, 3, 4, 6 and Table 3. The original
 204 station code represents the cruise codes from (SO239 and SO232-1). Depth refers to water
 205 depth (m) on deployment. Nodule presence/absence information is known only for stations
 206 D3 and D4.

| Deployment Code | Original Station Code | Depth (m) | Known geological features | Remarks | Residence Time (h:m:s) |
|-----------------|-----------------------|-----------|---|---|------------------------|
| C1 | SO239-33 | 4122 | Plains | German claim | 100:20:00 |

 210
 211
 212
 213
 214

215 ***Processing***

216

217 On recovery of the lander, all traps were disconnected and placed in pre-cooled (4°C) buckets
218 of filtered seawater. All specimens were washed on board in a cool-climate laboratory (4°C),
219 morphologically pre-sorted and fixed in molecular grade (95%) ethanol, before being stored
220 at -20°C.

221

222 Detailed sorting and identification was performed using the morphological species concept
223 (Futuyama, 1998) and the keys of Lowry & Killagen (2014) and Schulenberger & Barnard
224 (1976), to separate the samples into taxonomic “morphotypes”. The larger fraction (> 15 mm
225 length) has been identified to the lowest possible taxonomic resolution. Species not assigned
226 with certainty are denoted here by as affiliated species (e.g. *genus* aff. *species*) or conferred
227 species (e.g. *genus* cf. *species*).

228

229 Specimens with a size of less than 15 mm length were excluded from the analysis because
230 these were mostly juveniles and their morphological differences were not sufficiently
231 pronounced to allow an accurate identification to the species or even genus level. Some
232 pelagic amphipods were collected accidentally and omitted. Finally, genera containing
233 multiple (and as yet) unidentified species have been summarised as “spp.”

234

235 ***Statistical analyses***

236

237 Our null hypothesis (H_0) here is that there are no differences in the amphipod biodiversity of
238 the two basins. To test this hypothesis, we firstly calculated the alpha biodiversity of the two
239 basins was using the Simpson Index (D) (Simpson, 1949) (Appendix 4). Rarefaction was run
240 on the longer than 15 mm fraction using default parameters. Individual-based curves were
241 generated using the rarefy function of the vegan package in R 2.3.0 (R Core Team, 2013;
242 Gotelli, 2001) to compare species richness across all thirteen sampling stations and to test for
243 the completeness of sampling.

244

245 Secondly, to compare the beta biodiversity, we estimated the variability of the community
246 compositions between sites. The Bray-Curtis dissimilarity metric (Bray & Curtis, 1957), was
247 used to calculate differences between community compositions based on species densities,
248 and the results were then visualised in 2D using a Non-Metric Dimensional Scaling (NMDS)

249 plot. The ANOSIM function in the vegan package of R (R Core Team, 2013; Taguchi & Ono,
250 2005) was used to test the statistical significance of the differences in species compositions
251 between the two study areas.

252

253

254 Results

255

256 *Basin biodiversity*

257

258 In total, 6916 scavenging amphipods (> 15 mm) were collected from the thirteen trap
259 deployments in the two study areas, representing a total of seventeen morphotypes (Figure 2).
260 In the CCZ, we collected 3932 individuals, which represent ten morphotypes. Five of these
261 have been identified to the species level: *Abyssorchomene distinctus* (Birstein & Vinogradov,
262 1960), *Abyssorchomene gerulicorbis* (Shulenberg & Barnard, 1976), *Eurythenes sigmiferus*
263 (d'Udekem d'Acoz & Havermans, 2015), *Paralicella caperesca* (Shulenberg & Barnard,
264 1976) and *Paralicella tenuipes* (Chevreux, 1908). Two are affiliated to a species
265 (*Paracallisoma* aff. *alberti* and *Valettieta* cf. *gracilis*) and the remaining three are at least
266 affiliated to a genus (Tables 2a and 2b). The 2984 individuals from the DEA represent fifteen
267 morphotypes. Six of these have been identified to the species level: *Abyssorchomene*
268 *distinctus* (Birstein & Vinogradov, 1960), *Abyssorchomene gerulicorbis* (Shulenberg &
269 Barnard, 1976), *Eurythenes sigmiferus* (d'Udekem d'Acoz & Havermans, 2015), *Paralicella*
270 *caperesca* (Shulenberg & Barnard, 1976), *Parandaniexis mirabilis* (Schellenberg, 1929)
271 and *Tectoalopsis regelatus* (Barnard & Ingram, 1990). A further five which have been
272 affiliated to a species: *Eurythenes* aff. *gryllus*, *Eurythenes* aff. *magellanicus*, *Paracallisoma*
273 aff. *alberti*, *Stephonyx* sp. nov. aff. *arabiensis* and *Valettieta* cf. *gracilis* and the remaining
274 four identified to at least an affiliated genus (Tables 2a and 2b).

275

276 There are eight morphotypes shared between the basins: *Abyssorchomene distinctus* (Birstein
277 & Vinogradov, 1960), *Abyssorchomene gerulicorbis* (Shulenberg & Barnard, 1976),
278 *Abyssorchomene* spp., *Eurythenes sigmiferus* (d'Udekem d'Acoz & Havermans, 2015),
279 *Eurythenes* spp., *Paracallisoma* aff. *alberti*, *Paralicella caperesca* (Shulenberg & Barnard,
280 1976) and *Valettieta* cf. *gracilis* (Figure 2).

281

282 Two morphotypes were found only in the CCZ (*Hirondellea* sp. & *Paralicella tenuipes*
283 (Chevreux, 1908), and seven morphotypes were found only in the DEA (*Eurythenes* aff.
284 *gryllus*, *Eurythenes* aff. *magellanicus*, gen. aff. *Cleonardo*, *Parandania* sp., *Parandaniexis*
285 *mirabilis* (Schellenberg, 1929), *Stephonyx* sp. nov. aff. *arabiensis*, and *Tectoalopsis*
286 *regelatus* (Barnard & Ingram, 1990) (Table 2).

 313
 314
 315
 316

317 **Sampling completeness**

318

319 Due to differences in allocated ship-times (CCZ cruise being 52 days and the DEA cruise
320 being 29 days), the trap deployments were not identical, making it necessary to check the
321 effect of the different deployment times. **The resulting Catch Per Unit Effort (CPUE) plot**
322 **(Figure 3,) shows that there is no relationship between the length of time the trap was at the**
323 **seafloor and total number of amphipods caught. There is a moderate but statistically**
324 **insignificant negative correlation with increasing deployment times ($R = - 0.05, p = 0.551$).**

325

326

327 **Figure 3: Catch Per Unit Effort (CPUE) illustrating the correlation between sampling**
328 **time and number of individuals collected. Only the longer than 15mm fraction was**
329 **included here.**

330

331

332

333

334

335

336 The rarefaction results (Figure 4) show that the curves for nine stations reach a plateau,
337 indicating that sampling effort was sufficient to assess diversity levels. These include all CCZ
338 stations except C7. In contrast, four of the five curves for the DEA (stations D1, D2, D4 and
339 D5) are unsaturated.

340

341

342 **Figure 4: Species rarefaction curves for each of the 13 trap stations across both areas,**
343 **the Clarion-Clipperton fracture Zone and the DisCOL Experimental Area. Only**
344 **individuals longer than 15 mm were considered here.**

345

346

347

348

349

350 **Biodiversity**

351

352 Figures 5a and b show that the scavenging community in the CCZ is dominated by three
353 species, *A. distinctus* (Birstein & Vinogradov, 1960) (36%), *A. gerulicorbis* (Shulenberg &
354 Barnard, 1976) (18%) and *Paralicella caperesca* (Shulenberg & Barnard, 1976) (31%),
355 whereas, in contrast, the DEA scavenging community is dominated by a single species, *A.*
356 *gerulicorbis* (Shulenberg & Barnard, 1976), accounting for almost 60% of all specimens.
357 The Simpson Index (D) for the entire CCZ area is (with 0.73), higher than the 0.62 that was
358 calculated for the whole of the DEA area (Table 3). The biodiversity of each individual
359 station was further explored (Table 3). In the CCZ, the lowest biodiversity was found at C3
360 and C6 ($D = 0.23$) and the highest at C2 ($D = 0.67$), respectively. In the DEA, the lowest
361 biodiversity of $D = 0.36$ was found at station D1 (the site of the actual disturbance) and just
362 south of the disturbance site at D2 (0.21), while the highest biodiversity was observed at D5
363 ($D = 0.61$) (Table 3).

392

393

394

395 **Species composition**

396

397 The NMDS shows that the communities of the two basins are clearly separated (ANOSIM: p
398 = 0.002); Figure 6). The disturbed area in the DEA (D1) is showing a clear difference to the
399 four reference areas (D2 - 5). When the communities between the two basins are compared,
400 D2 appears to be most similar to the CCZ community, and more specifically to C6, C7 and
401 C8. The reliability of the data ranking is supported by a low stress value of 0.01.

402

403

404 **Figure 6 : NMDS plot** showing the beta biodiversity (dis/similarities) for each of the thirteen
405 amphipod trap sampling stations associated with the two basins, Clarion-Clipperton fracture
406 Zone (CCZ) (black) and the DisCOL Experimental Area (DEA) (red). Data are supported by
407 a low stress value of 0.01.

408

409

410 **Discussion**

411

412 *An unexplored ecosystem*

413 Although the most recent and comprehensive analysis of the Animal diversity of the World's
414 oceans estimates a total of less than a million species over all depths (Appeltans et al. 2012),
415 it is not currently known how many species inhabit the deep-sea. Regarding amphipods, only
416 328 benthic, demersal and benthopelagic species, belonging to 144 genera and 39 families.
417 Over 7000 marine amphipod species have been found below 2000 m. These numbers are
418 reduced to 173 known species, 87 genera and 37 families at depths below 3000 m, and 100
419 known species, 66 genera and 31 families are known to occur below 4000 m (Vader 2005;
420 Brandt et al, 2012).

421

422 *Lysianassoidea and their biogeography*

423

424 The superfamily Lysianassoidea constitutes an important part of the abyssal amphipod fauna.
425 Also, in our sampling, lysianassoid amphipods were collected in large numbers (99% of the
426 samples taken in both basins). As a superfamily, they comprise 23% of all the species found
427 below 2000 m, 35% of the species found below 3000 m and 31% of the species found below
428 4000 m (Brandt et al. 2012).

429

430 Many species in the Lysianassoidea occur in multiple abyssal basins, and some even have
431 worldwide distributions (Thurston 1990). Despite the Ocean Biogeographic Information
432 System (OBIS) database containing 615,650 records of Amphipoda, many of these are shelf
433 or pelagic species, with very few records from the CCZ and DEA (OBIS, 2017). Here, we
434 provide additional data for the known bathymetric range of the seven amphipods which we
435 have identified to species level (*Abyssorchomene distinctus* (Birstein & Vinogradov, 1960),
436 *Abyssorchomene gerulicorbis* (Shulenberger & Barnard, 1976), *Eurythenes sigmiferus*
437 (d'Udekem d'Acoz & Havermans, 2015), *Paralicella caperesca* (Shulenberger & Barnard,
438 1976), *Paralicella tenuipes* (Chevreux, 1908), *Parandaniexis mirabilis* (Schellenberg, 1929)
439 & *Tectovalopsis regelatus* (Barnard & Ingram, 1990) (Table 2b). In addition, we have found
440 two possibly new species of *Eurythenes*, previously not known from these basins, which we
441 plan to analyse further in the future.

442 While we only sampled *Hirondellea* sp. and *Paralicella tenuipes* (Chevreux, 1908) in the
443 CCZ, *Eurythenes* aff. *gryllus*, *Eurythenes* aff. *magellanicus*, gen. aff. *Cleonardo*, *Parandania*
444 sp., *Parandaniexis mirabilis* (Schellenberg, 1929), *Stephonyx* sp. nov. aff. *arabiensis*, and
445 *Tectovalopsis regelatus* (Barnard & Ingram, 1990) only in the DEA, we cannot conclude
446 based on the current data only if these species are unique to their respective basins without
447 confirming these distribution patterns with additional sampling campaigns.

448

449 Despite the sampling campaign in the CCZ being twice as long as the DEA, the number of
450 individuals/species collected does not correlate positively with deployment effort. We posit
451 that this is rather an effect of abiotic and organic factors, such as the productivity-driven
452 gradients in the CCZ, which decrease from East-West and from North-South (Hannides &
453 Smith, 2003).

454

455 ***Biodiversity within basins***

456

457 Figures 5a & b show clearly that the DEA scavenging community has reduced abundances of
458 all species including *A. distinctus* (Birstein & Vinogradov, 1960) (1%) and *P. caperesca*
459 (Shulenberger & Barnard, 1976) (7%), and is now dominated by a single species, *A.*
460 *gerulicorbis* (Shulenberger & Barnard, 1976), accounting for 60% of the DEA community.
461 This indicates an interesting resilience and flexibility in the latter species. Similar patterns
462 have been observed in Potter Cove (Seefeldt et al. 2017), where following glacial retreat, a
463 change in sedimentation rates led to the dominance of a single amphipod scavenging species,
464 *Cheirimedon femoratus* (Pfeffer, 1888).

465

466 The assemblages of the two basins have some overlap in their biodiversity (as is exemplified
467 by the eight shared morphotypes). However, the sampling stations and the two basins as a
468 whole are heterogeneous in their species compositions.

469

470 Thus, we can observe some negative influence (possibly attributed to the disturbance in the
471 DEA) on the scavenging amphipod community. This reduced biodiversity is reflected in the
472 higher Simpson Index (D) for the CCZ (0.73) as compared to the DEA ($D = 0.62$; Table 3).

473

474 To explore whether this reduced diversity in the DEA was truly a result of the simulated
475 disturbance, D was also calculated for each sampling station within each basin (Table 3).

476 In the CCZ, the APEI (C8) shows a moderate level of biodiversity ($D = 0.44$), indicating that
477 it is not optimally-placed for representing the biodiversity of the scavenging amphipod
478 community of the CCZ. Additionally, this pre-existing lower biodiversity (in comparison to
479 the contractor claim areas), indicates that the APEI may not serve well as a refugium for
480 amphipods post-disturbance. However, due to the fact that only one of the eight APEIs have
481 been investigated thus far, this APEI along with the remaining eight APEIs would need to be
482 (re-) sampled.

483

484 Within the DEA, the lowest biodiversities are observed at the site of the disturbance (D1) and
485 south of it (D2; Table 3), indicating that the reduced biodiversity in the DEA could indeed be
486 caused by the simulated disturbance in 1989 (Thiel, 1992).

487

488 The highest abundances in the DEA were collected from station D5 ($n = 717$); this station
489 also has the highest Simpson Index within the DEA ($D = 0.61$) (Table 3). Side-scan sonar
490 imaging shows a seamount range to the North West (NW) of the disturbed area (D1)
491 (Appendix 3). Although the relief change is only 150m, the range extends laterally for several
492 kilometres (SO242-1 Cruise report, 2016) hampering dispersal across barriers such as sills,
493 canyons and ridges (Smith, et al. 2006; Blankenship et al. 2006; Etter et al. 2011). However,
494 recent studies have shown that due to their mobile nature, geographic isolation alone would
495 not pose a true barrier to benthic-pelagic amphipod species (Havermans, 2016; Ritchie et al.
496 2017), and thus, cannot explain why such a high number of large scavenging individuals was
497 collected at station D5.

498

499 ***Community similarities***

500

501 Scavenging amphipods are resilient and dispersive, but most importantly, they are highly
502 mobile (Ingram and Hessler 1983; Lörz et al. 2018). Often driven by their search for erratic
503 deposited feeding opportunities (Smith et al. 1989), they are probably less constrained by
504 local environmental abiotic conditions and seafloor topography.

505

506 Beta diversity can be regarded as the dissimilarities in species composition between spatially
507 different communities. As an indication for beta biodiversity, the NMDS (Figure 6) shows a
508 significant separation in the similarity index between the two basins (ANOSIM $p = 0.002$).
509 However, despite the dispersive and resilient nature of scavenging amphipods, their

510 biodiversity appears to have been affected by the disturbance experiment as evidenced by the
511 NMDS (Figure 6), where the disturbed area (D1) and the area closest to it (D2) are separated
512 from the remaining three reference sites (D3, D4 and D5).

513

514 In the CCZ, stations C1, C2, C3, C4 and C5 form one cluster in the NMDS (Figure 6), and
515 stations C6, C7 and C8 a second cluster. The CCZ is a geomorphologically very
516 heterogeneous region, with seamounts of 200 m altitude running from north-south. A barrier
517 of this height would be expected to affect sedimentation rates, nodule presence and currents.
518 Furthermore, the difference in depth from the eastern edge (3950m) and the western edge
519 (5150 m) is more than 1200 m. These combined factors very likely give rise to different
520 trends in species composition (Glover, et al. 2015). However, since it has been established
521 that benthic-pelagic amphipods are less sensitive to such barriers (Havermans, 2016), at this
522 stage, other biotic (e.g. the productivity gradient) and abiotic factors causing this separation
523 cannot be excluded as alternative explanations.

524

525 *Dispersal and connectivity*

526

527 Whilst the NMDS (Figure 6) illustrates a visual separation of the two basins, there is also
528 some similarity in the amphipod fauna between the two areas, (as is obvious by the eight
529 shared species), indicating that the dispersal extent for these eight species might range up to
530 at least 3000 km. However, this hypothesis will need to be confirmed with subsequent
531 molecular analyses.

532

533

534 Abyssal amphipods have been shown to be able to travel actively at speeds of almost 4
535 cm/sec (Laver, 1985), even at temperatures as low as 3°C (Kankaanpää et al. 1995). It is
536 obvious that they are sufficiently strong to swim up weak currents since they can be found
537 several hundred meters above the seafloor searching pelagically for mates (e.g. *Eurythenes*
538 *gryllus* occurring up to 1800 m above the seafloor) (Thurston 1990; Havermans et al. 2013)
539 or following food-falls (Baldwin and Smith 1987).

540

541 However, it is apparent that the dispersal of abyssal amphipods is not always contingent on
542 current direction, but also on passive dispersal. Amphipods can also be carried passively over
543 long distances by stronger currents e.g. (the circumpolar current of the Southern Ocean)

544 (Laver et al. 1985), but even weaker deep-sea currents have been suggested as a mechanism
545 for deep-sea dispersal of amphipods (e.g. *Eurythenes gryllus* (Schüller and Ebbe 2007)). This
546 coupled with their ability to follow odour-plumes (Ide et al. 2006; Premke, 2003),
547 significantly increases the probability and extent of their dispersal (Conlan 1991; Highsmith,
548 1985). Specialist feeding adaptations for several species in our assemblages have been
549 reported in Havermans & Smetacek, 2018). For example, the semi-tubular flap-like molars of
550 the genera *Hirondellea* and *Eurythenes*, and the distendable foregut (*Abyssorhomene*) and
551 midgut (*Paralicella*). It is not clear from our study in the absence of POC data for the areas of
552 the trap deployments whether the biogeography of these specialised feeders is linked to the
553 productivity gradients in these two basins.

554

555 The lack of a clear dispersal pattern is obvious from Figure 6, where station D2 is the station
556 clustering closest with the CCZ basin in terms of species composition despite the fact that
557 station D5 is geographically the shortest distance away from the CCZ.

558

559 Recent research on *Eurythenes gryllus* has demonstrated that it thrives in every ocean with a
560 wide (pelagic – hadal) depth range. However, assumptions that individual morphotypes of
561 this species belong to the same genetic lineage have been challenged (Havermans et al. 2013
562 & Havermans, 2016). Ritchie et al. (2016) demonstrated with microsatellite markers
563 heterozygote deficiency in *Paralicella tenuipes* (Chevreux, 1908), which they attributed to
564 cryptic diversity. It is likely that the connectivity of the eight species we observed as being
565 shared between the CCZ and DEA (based on traditional morphological methods), can be
566 explained by the presence of one or more cryptic amphipod species, which are being tested in
567 our future molecular research.

568

569 Unfortunately, in the absence of data on deep-sea currents in the study area, especially
570 between the CCZ and DEA, it is not yet possible to fully explain the drivers and mechanisms
571 of amphipod dispersal between these particular basins.

572

573

574

575

576

577

578 *The DisCOL Experimental Area as a proxy*

579

580 Higher abundances of scavenging amphipods were collected from the CCZ (3932
581 individuals) as opposed to the DEA (2984 individuals). Yet, we have identified more
582 morphotypes in the DEA (18) than in the CCZ (10), indicating that the DEA is more
583 speciose, and thus, more biodiverse.

584

585 Although the DEA is more speciose, many of its morphotypes were collected in low
586 abundances, with several of these being singletons or doubletons (collected from one or two
587 sampling stations only). This is reflected in the rarefaction curves (Figure 4), which indicate
588 thorough sampling in the CCZ with all but station C7 reaching asymptotes. In contrast, four
589 stations in the DEA (D1, D2, D4 and D5) are unsaturated. This pattern suggests firstly that
590 the less abundant species which are present at fewer stations only may not necessarily be rare
591 species and secondly, that there could be as yet undetected biodiversity in the DEA.

592 Therefore, the effects of mining impact could be even more pronounced than we observed in
593 this study. However, as the seafloor environment is subject to seasonal fluctuations (Billett et
594 al. 1983), it is hard to predict exactly what the effects will be at this stage.

595

596 Our preliminary (basin-scale) comparison of the scavenging communities of the two study
597 areas shows that even if the DEA is a small-scale disturbance experiment, it is a very diverse
598 area. Thus, the DEA is a well-chosen site for monitoring the impacts of disturbance and
599 instrumental in its role as a proxy to assess impending mining activities in the CCZ.

600

601 *Future research*

602

603 At several stations in both basins, we collected amphipods in very high abundances (C1, C8,
604 D3 & D5) (Table 2b). Since biotic production is contingent on the sinking flux of particles
605 from the euphotic zone (Sweetman, 2017), the biodiversity differences at each of the thirteen
606 stations could be driven by Particulate Organic Carbon (POC) or erratic whale-falls (Smith et
607 al. 1989). However, not all feeding behaviour of scavenging amphipods is based on
608 opportunistic or erratic availability of nutrients (Havermans & Smetacek, 2018). During
609 future sampling campaigns, the POC of these areas should be monitored, along with
610 experiments on different types of food-fall in addition to obtaining side-scan sonar and

611 abiotic data. This will provide a more comprehensive view of the food types required for
612 these species to thrive in the deep sea.

613

614 It is not clear from our results whether substrate type (i.e. nodule/non-nodule) has any effect
615 on the amphipod communities (Smith and Demopoulos, 2003) since this kind of data is only
616 available for stations D3 and D4. To answer this question, resampling of the study areas in
617 combination with an Ocean Floor Observation System (OFOBS) (video/camera) is required.

618

619 Although our study only addresses the scavenging amphipod species longer than 15 mm, we
620 already find indications for a disturbance effect in the DEA. It is obvious that scavenging
621 amphipods are only one of several benthic-pelagic indicator groups. Other truly benthic
622 groups such as sponges or less dispersive amphipods (e.g. collected by epibenthic sledge
623 (EBS)) may demonstrate an even more pronounced impact of mining activities and should be
624 investigated in future studies.

625

626 With the application of molecular techniques to identify cryptic species (Delić et al, 2017),
627 more realistic estimates of biodiversity can be obtained (Schön et al. 2012), improving our
628 current knowledge of the biodiversity of this area. If these improved estimates of biodiversity
629 also include cryptic species, it is possible that the biological impact of manganese nodule
630 mining on amphipod and other deep-sea faunal communities may turn out to be even higher.

631 **Conclusions**

632

633 In summary, this study on the scavenging amphipod community of two abyssal oceanic
634 basins has demonstrated that amphipods are present in high abundances across the CCZ and
635 DEA, with eight shared species and some species possibly being unique to their respective
636 basin.

637 Our results have indicated that the simulated mining experiment probably had an impact on
638 the biodiversity of these scavenging amphipods, as demonstrated by the low *D* of the DEA
639 overall, at the disturbance site itself (D1), and the 60% dominance of *A. gerulicorbis*
640 (Shulenberger & Barnard, 1976) in this region.

641 Given the scarcity of sampling and industry experience of marine habitats at these depths, the
642 formulation of effective regulations is challenging (International Seabed Authority, 2017).

643 Nonetheless, our study provides the first results on possible effects of disturbance activities
644 on the abyssal amphipod biodiversity of deep-sea basins.

645 **Sample and data availability**

646 Biological samples pertaining to this manuscript are stored at the Royal Belgian Institute of
647 Natural Sciences, and the data discussed in the manuscript are submitted to PANGEA.

648 **Acknowledgements**

649

650 The authors would like to acknowledge the Belgian Science and Policy Office (BELSPO) and the
651 German Federal Ministry of Research and Education for funding. We would also like to thank the
652 crew of the Research Vessel “Sonne”, the University of Ghent (Ghent, Belgium) and Zohra
653 Elouaazizi (Brussels, Belgium) for help in the lab. This study would not have been possible without
654 their support.

923 **Figure captions**

924

925 **Figure 1: Geographic locations of the two study areas, the Clarion-Clipperton**
926 **fracture Zone (CCZ) (Northeast Pacific) and the DISTurbance and re-COLonisation**
927 **(DisCOL) Experimental Area (DEA) (Peru Basin, Southeast Pacific).** There are nine
928 Areas of Particular Ecological Interest (APEIs) in the CCZ region, which are illustrated
929 by 400 x 400 km² white boxes. Grey boxes indicate the various contractor claim areas in
930 the CCZ. We deployed eight amphipod traps across the CCZ, which is 16,000 km² and
931 7000 km wide, and five in the DEA, which encompasses 11 km² with a width of 4 km.

932

933 **Figure 2: Histogram showing the species assemblage for the scavenging community**
934 **in the Clarion-Clipperton fracture Zone (CCZ) (black) and the DisCOL**
935 **Experimental Area (DEA) (grey).** The abundances of 17 morphotypes are shown.

936

937 **Figure 3: Catch Per Unit Effort (CPUE) illustrating the correlation between**
938 **sampling time and number of individuals collected.**

939

940 **Figure 4: Species rarefaction curves for each of the 13 trap stations across both**
941 **areas, the Clarion-Clipperton fracture Zone and the DisCOL Experimental Area.**
942 Only individuals longer than 15 mm were considered here.

943

944 **Figures 5a and b: Relative species abundances in the Clarion-Clipperton fracture**
945 **Zone and the DisCOL Experimental Area.** These abundances represent the longer than
946 15mm fraction of the scavenging amphipod community only.

947

948 **Figure 6: NMDS plot showing the beta biodiversity (dis/similarities) for each of the**
949 **thirteen amphipod trap sampling stations associated with the two basins, Clarion-**
950 **Clipperton fracture Zone (CCZ) (black) and the DisCOL Experimental Area (DEA) (red).**
951 Data are supported by a low stress value of 0.01.
