Associate Editor Comments – Author Responses

L18-22 make only one sentence, no need to repeat twice "keeling plote & miller Tans.." in the abstract

These two sentences were combined to avoid the repetition of 'Keeling plot and Millter-Tans plot'. P.1, L. 19-21.

L21: "the similar 13C of DIC source": what DIC sources and where, all rivers? Rephrase

The sentence was deleted during the revision.

L22-23 not clear what you mean by "pH and DIC speciation on measured 13C-DIC"; the sentence about 13C DIC in the abstract can be more focused on main result

This sentence was deleted to maintain the focus on main results of the study, i.e, stable isotopes of DIC and its spatial variability. P. 1, L.16-25

L24-25 it seems strange that 13C DIC trends are not mentioned here: depleted when heterotrophic respiration and enriched in autotrophic sites?

Spatial variability of $\delta^{13}C_{DIC}$ was given now. Relatively enriched $\delta^{13}C_{DIC}$ values were found in rivers of the southeast region in which autotrophic production is dominant. Whereas depleted $\delta^{13}C_{DIC}$ values were observed in the other monsoonal rivers where heterotrophic respiration is predominant. P.1, L 16-25.

L38-40 you basically repeat what was said before in the abstract without giving more detailed interesting information such as : where is autotrophy favoured (and why), where is heterotrophy favoured and why?Abstract could be improved to provide more precise information, avoiding too general statements, and repetitions

Repeated sentences were deleted and detailed information on the spatial variability of $\delta^{13}C_{DIC}$ was given. Too general statements were deleted to maintain the focus of our main results.

L58 and L68 Raymond et al 2013 is not the appropriate reference for DIC export fluxes to coastal regions

Raymond et al. (2008) at L 58 was deleted and Richey et al. (2002) was added. P. 2, L. 53

Raymond et al. (2013) at L 68 was replaced with Joesoef et al. (2017). P. 3, L. 63

L105 it is not clear here if "equilibrium" is the right word, rather than "isotopic equilibration". If "Isotopic equilibration with the atmosphere" refers to the changes in 13C-DIC due to selective 12CO2 and 13CO2 fluxes at the water-air interface, then the process is very significant when water pCO2 is high such as in small streams. (Deirmendjan and Abril 2018 JoH, and refs therein from J. Barth group). Please update the statements here L105-110.

The statements given at L 105-110 were modified. "Though, rivers are generally in disequilibrium with atmospheric CO_2 (Raymond et al., 2013) and emit CO_2 to atmosphere due to oversaturation (Oquist et al., 2009; Campeau et al., 2017), the isotopic equilibration between the DIC and CO_2 in the atmosphere significantly influences the $\delta^{13}C_{DIC}$ in rivers (Abongwa and Atekwana, 2014; Deirmendjian and Abril, 2018) due to selective fluxes of $^{12}CO_2$ and $^{13}CO_2$ at the water-air interface. Hence, the influence of biogeochemical processes within the rivers must be considered while interpreting the $\delta^{13}C_{DIC}$ results for identification of DIC sources". P. 4-5, L. 100-106

L154 remove "rather than headwaters" no need

"rather than headwaters" was removed. P. 6, L.150-151

L225 and L382under-saturation, not "unsaturation"

Sorry for the mistake. 'unsaturation' at L 225 and L382 were corrected to "under-saturation" P. 9, L. 219 and P. 15, L. 377

L300 exchange of CO2 with the atmosphere, and not "exchange with atmospheric CO2"

It was changed to "exchange of CO_2 with the atmosphere" P. 12, L. 294

L323 "Bouillon" not "bouvillion"

Sorry for the mistake: It was corrected to "Bouillon" P. 13, L. 317

L354 "interpreted "as" not "to"

The sentence was changed to "…..interpreted 'as' the influence of in-stream processes" P. 14, L. 348

L372 "DIC … is largely contributed by" please rephrase

The sentence was rephrased as "These results indicated that chemical weathering of carbonate and silicate minerals by soil CO_2 (-10 to -9‰) is the major source of DIC in the Indian rivers." P. 15, L. 366-367

L394 "the remaining into the Arabian Sea" please rephrase

The sentence was rephrased as "Nearly three fourth of this amount (7.8 Tg) reaches to the Bay of Bengal while the Arabian Sea receives only one fourth (2.5 Tg)".
P. 16, L. 387-388

L397 not sure "far less" here is correct English
"far less" was changed to "lower" P. 16, L. 391

What does shaded area mean in table 1?

It was explained in the caption of the table now. "Rivers located in the northern region (north of 16^{o}N) of India were shown by the shaded (grey) area. Of these shaded rivers, Mahisagar to Narmada (west flowing rivers) and Godavari to Haldia (east flowing rivers) represent the rivers of the northwestern (NW) and northeastern (NE) regions of India respectively. **P. 30, L. 965-968**

Fig 1 is of poor graphical quality, please improve

Quality of the figure was improved. Names of all the rivers sampled are clearly visible now. The quality of labels for different types of soils was improved.

Fig2 I could not understand why degassing at pH <6.4 and at pH > 6.4 have different effect on 13C-DIC. Degassing will make 13C-DIC converge to about zero per mil
Weathering by "carbonic acid derived from dissolution of atmospheric CO2" is something strange, and likely not significant in soils where most of the CO2 comes from soil respiration. Where do these statements come from? Please revise this figure and improve the legend

Figure 2 was modified and the legend was improved. Weathering of carbonate and silicate rocks by carbonic acid formed by the dissolution of atmospheric CO_2 was deleted as it is minor in soils. Biogeochemical processes influencing the δ^{13}C-DIC were also modified.

Export fluxes of dissolved inorganic carbon to the Northern Indian Ocean from the Indian monsoonal rivers

Abstract. Rivers are an important source of dissolved inorganic carbon (DIC) to the adjacent coastal waters. In order to examine the spatial variability in the distribution and major sources of DIC in the Indian monsoonal rivers and to quantify their export flux to the north Indian Ocean, 27 major and medium rivers were sampled during the discharge period. Significant spatial variability ~~of DIC~~in concentrations of DIC (3.4 – 73.6 mg l^{-1}) was observed and it is attributed to spatial variations in the precipitation pattern, size of rivers, pollution, and lithology of the catchments. The stable isotopic composition of ~~bulk~~ DIC ($\delta^{13}C_{DIC}$) also showed strong spatial variability (-13.0 to -1.4‰) in the Indian monsoonal rivers with r~~. R~~elatively depleted $\delta^{13}C_{DIC}$ values ~~were observed~~ in rivers of the northwestern ~~region~~of India (-11.1±2.3‰) ~~while~~and enriched values ~~were found in rivers of~~in the southeastern ~~region of~~ India (-3.5±2.3‰). ~~indicates that predominant contribution of DIC is from chemical weathering of carbonate and silicate minerals by soil CO_2. As the in-stream processes significantly alter the $\delta^{13}C_{DIC}$ in rivers,~~Results of the least square linear regression models of ~~two different graphical mixing models techniques,~~ Keeling ~~plot~~ and Miller-Tans plots~~, were used to approximate the $\delta^{13}C$ of DIC source. Approximated $\delta^{13}C$ values (-2.0 to -3.0‰)~~ indicated that chemical weathering of carbonate and silicate minerals by soil CO_2 is the major source of DIC in the Indian monsoonal rivers. Spatial variability in the deviation of $\delta^{13}C_{DIC}$ from the approximated $\delta^{13}C$ of source ~~indicated that~~may probably due to dominant autotrophic production ~~predominantly controls the $\delta^{13}C_{DIC}$~~ in rivers of the southeast region whereas, heterotrophic decomposition of organic matter largely influences in the other Indian

monsoonal rivers ~~Least square linear regression models of both Keeling and Miller Tans plots approximated the similar $\delta^{13}C$ of DIC source (-2.0 and -3.0‰ respectively). Further, the $\delta^{13}C$ of CO_2 was approximated in order to filter the influence of pH and DIC speciation on the measured $\delta^{13}C_{DIC}$. Our results indicated that DIC in the Indian rivers is contributed by chemical weathering of carbonate minerals, but largely influenced by autotrophic production in rivers from the southeast region and heterotrophic decomposition of organic matter in the other Indian monsoonal rivers.~~ It is estimated that the Indian monsoonal rivers annually export ~10.3 Tg of DIC to the northern Indian Ocean, of which the major fraction (75%) enters into the Bay of Bengal and the remaining reaches to the Arabian Sea. This is consistent with the freshwater flux which is three times higher to the Bay of Bengal (~378 km^3 yr^{-1}) than to the Arabian Sea (122 km^3 yr^{-1}). Despite discharge from the Indian monsoonal rivers account for only 1.3% of the global freshwater discharge, they disproportionately export 2.5% of the total DIC export by the world major rivers. Despite rivers from the SW region of India export an order of magnitude lower DIC (0.3 Tg yr^{-1}) than the rivers from other regions of India, the highest yield of DIC was found in the former and it is attributed to intense precipitation (~3000 mm), favorable natural vegetation of tropical moist deciduous and tropical wet evergreen and semi evergreen forests, ~~-~~tropical wet climate, high soil organic carbon and the dominance of red loamy soils in catchments of the rivers from SW region. ~~Our study demonstrates that significant spatial variability of the hydrological, lithological and environmental conditions in the catchments and in-stream processes (autotrophic production and heterotrophic decomposition of organic matter) strongly controls the DIC in the Indian monsoonal rivers.~~

Keywords: dissolved inorganic carbon, export flux, Indian rivers, Bay of Bengal, Arabian Sea, North Indian Ocean

1. Introduction

Dissolved inorganic carbon (DIC) is one of the major constituent of carbon species in rivers. DIC in rivers mainly originates from the geogenic (weathering of carbonate and silicate rocks) and biogenic (decomposition of organic matter in soils) sources (Meybeck, 1987; Mook and Tan, 1991; Gaillardet et al., 1999, Dessert et al., 2001; Viers et al., 2007; Raymond et al., 2008; Tamooh et al., 2013). The former consumes atmospheric carbon dioxide (CO_2) while the latter releases CO_2 fixed by the terrestrial plants. In addition to these major sources in the catchment, DIC is also contributed by various physical and biological processes within the rivers. For instance, heterotrophic decomposition of organic matter, photo-oxidation of dissolved organic carbon (DOC), autotrophic respiration and dissolution of atmospheric CO_2 contribute DIC to rivers. On the other hand, autotrophic production by aquatic plants (photosynthesis) and evasion of CO_2 to atmosphere with draw DIC from rivers. All these processes in the catchments and within the rivers are strongly coupled to atmospheric CO_2 because they act as either sink or source of atmospheric CO_2 (e.g. Berner et al., 1983; Mook and Tan, 1991; Gaillardet et al., 1999; ~~Raymond et al., 2008~~Richey et al., 2002). The DIC in rivers and its export to the coastal oceans is thus intimately linked to the global carbon cycle (Campeau et al., 2017)

Riverine export fluxes of DIC to coastal regions of the world oceans have been estimated on the global (Gaillardet et al., 1999; ~~Raymond et al., 2013~~) and regional scales (Richey et al., 2002; Wallin et al., 2013; Crawford et al., 2014; Campeau et al., 2014; Kokic et al., 2015) to understand the component of DIC in the global carbon budget. Annual export flux of DIC from the world major river systems to the gloabal ocean has been estimated as ~327 - 385 Tg ($1Tg=10^{12}g$) (Ludwig et al., 1998; Meybeck and Vorosmarty, 1999). However, many of the regional studies on DIC export fluxes were limited only to the major river systems (e.g. Gaillardet et al., 1999; ~~Raymond et al., 2013~~Joesoef et al., 2017), for example, the Mississippi (Raymond and Cole, 2003; Raymond et al., 2008; Cai et al., 2008),

Changjiang and Pearl (Cai et al., 2008) and Congo (Wang et al., 2013) rivers etc. Regional studies on the riverine export fluxes of DIC are very important for the global carbon cycle and budget as the export fluxes are largely dependent on the hydrological, lithological and environmental conditions, which are highly variable on the regional scales. However, DIC measurements are still lacking in several medium rivers from different regions of the world in general and Asia in particular.

Studies on the sources and export fluxes of DIC from the Indian rivers are very limited. Though DIC measurements were conducted in some Indian estuaries, for example, Mandovi and Zuari (Sarma et al., 2001), Godavari (Sarma et al., 2011), Cochin (Gupta et al., 2009; Bhavya et al., 2018), Hooghly (Mukhopadhyay et al., 2002; Samanta et al., 2015), Mahanadi (Pattanaik et al., 2017) and Chilka (Gupta et al., 2008; Muduli et al., 2013), they were confined only to the internal cycling of DIC and exchange of CO_2 at the air-water interface, but not focused on the sources and export fluxes of DIC. The major sources of DIC in the Indian rivers remain unclear, except only a couple of rivers, Krishna (Das et al., 2005; Laskar et al., 2014) and Ganges (Samanta et al., 2015). Further, the quantity of annual DIC export by the Indian rivers to the coastal regions is unknown. Here, we made an attempt to understand the major sources of DIC in the Indian monsoonal rivers (Fig. 1) using $\delta^{13}C_{DIC}$ as a potential tracer, and to estimate the riverine export flux of DIC to the north Indian Ocean from the Indian subcontinent.

The stable isotopic composition of DIC ($\delta^{13}C_{DIC}$) is widely used to identify the major sources of DIC in the aquatic systems (e.g. Singh et al., 2005; Tamooh et al., 2013; Samanta et al., 2015; Zou, 2016). The isotopic composition of DIC originated by dissolution of atmospheric CO_2 is about 0‰ (Coplen et al., 2002) whereas it is about -27 to -26‰ if the DIC is derived from oxidation of organic matter produced by C_3 plants (O'Leary, 1988). The $\delta^{13}C$ of DIC generated by carbonic acid (formed by soil CO_2 dissolution) weathering of

105 silicates is about -21 to -17‰ (Solomon and Cerling, 1987) while it is in the range of -10 to -
106 9‰ for carbonate rocks because half of the carbon comes from carbonate rocks (0‰, Land,
107 1980) during weathering. The weathering of silicate and carbonate minerals yield $\delta^{13}C_{DIC}$ in
108 the range of -8 to -7‰ and -4 to -3‰, respectively, if the carbonic acid formed by the
109 dissolution of atmospheric CO_2. Though the $\delta^{13}C$of DIC derived from different sources is
110 well separable (Deines et al., 1974), the isotopic fractionation by in-stream physical and
111 biological processes alters the $\delta^{13}C$ of DIC source (Fig. 2). For example, photosynthesis and
112 ~~equilibration with atmospheric CO_2~~degassing enriches (O'Leary, 1988; Finlay, 2004; Parker
113 et al., 2005, 2010; Polsenaere and Abril, 2012; Venkiteswaran et al., 2014) while the
114 heterotrophic decomposition of organic matter and photo-oxidation of dissolved organic
115 carbon depletes the $\delta^{13}C$ of DIC (Opsahl and Zepp, 2001; Finlay, 2003; Waldron et al., 2007;
116 Vahatalo and Wetzel, 2008) (Fig. 2). ~~Of these processes, equilibrium with atmospheric CO_2~~
117 ~~is of less significance because~~Though, rivers are generally in disequilibrium with atmospheric
118 CO_2 (Raymond et al., 2013) and emit CO_2 to atmosphere due to oversaturation (Oquist et al.,
119 2009; Campeau et al., 2017), the isotopic equilibration between the DIC and CO_2 in the
120 atmosphere significantly influences the $\delta^{13}C_{DIC}$ in rivers (Abongwa and Atekwana, 2014;
121 Deirmendjian and Abril, 2018) due to selective fluxes of $^{12}CO_2$ and $^{13}CO_2$ at the water-air
122 interface. ~~Nevertheless~~Hence, the influence of ~~internal~~ biogeochemical processes within the
123 rivers must be considered while interpreting the $\delta^{13}C_{DIC}$ results for identification of DIC
124 sources. The main objectives of this study are to (i) identify the major sources of DIC in the
125 Indian monsoonal rivers, (ii) estimate the export flux and yield of DIC to the north Indian
126 Ocean and (iii) examine the major processes in the catchments and within the rivers
127 controlling DIC in the Indian monsoonal rivers.

128 **2. Study region, sampling and methods**

129 **2.1 Study Area**

The Indian peninsula bifurcates the north Indian Ocean into the Bay of Bengal and the Arabian Sea. Although these two basins occupy the same latitudinal belt, their oceanographic processes were reported to be remarkably different due to higher freshwater flux into the Bay of Bengal (1.63×10^{12} m^3 yr^{-1}) than to the Arabian Sea (0.3×10^{12} m^3 yr^{-1}; Subramanian, 1993; Gauns et al., 2005). The large freshwater influx leads to the formation of a strong vertical salinity stratification in the Bay of Bengal (Varkey et al., 1996) that prevents vertical mixing of nutrient rich sub-surface water with the surface (Prasanna Kumar et al., 2004). As a result, the Bay of Bengal is considered to be relatively less productive (Prasannakumar et al., 2002) than the adjacent Arabian Sea, which is one of the highly productive zones in the world (Madhupratap et al., 1996; Smith, 2001; Barber et al., 2001) due to injection of nutrients into the surface through the seasonal upwelling and convective mixing (Shetye et al., 1994; Madhupratap et al., 1996; Muraleedharan and Prasannakumar, 1996).

Discharge from the Indian monsoonal rivers is largely fed by the monsoon induced precipitation over the Indian subcontinent, which receives >80% of its annual rainfall during the southwest (SW) monsoon period (June-September) (Soman and Kumar, 1990). Though some amount of rainfall occurs during the northeast (NE) monsoon (December-March), it does not generate discharge as it will be stored within the dam reservoirs for domestic, industrial and irrigation purposes. Discharge from the Indian monsoonal rivers mainly occurs during the SW monsoon season (Vijith et al., 2009; Sridevi et al., 2015) hence, these rivers are called as monsoonal rivers. Since the major portion of the annual freshwater discharge occurs only during the SW monsoon, the entire estuary is filled with freshwater (Vijith et al., 2009; Sridevi et al., 2015) during this period. As discharge is small during the rest of the year, the discharge during the SW monsoon (wet period) is considered to be equivalent to the annual discharge of the monsoonal rivers. Based on rainfall intensity, forest cover, vegetation

and soil type in the catchment, rivers sampled in the present study were categorized into 4 groups, namely the northwest (NW), southwest (SW), southeast (SE) and northeast (NE) rivers of India (Fig. 1). The SW region of India is characterized by the intense rainfall during SW monsoon (~3000 mm) following the NE (1000-2500 mm), SE (300-500 mm) and NW (200-500 mm) regions of India (Soman and Kumar, 1990). The SW rivers drain red loamy soils while the NW rivers drain black soils. Except the major rivers Godavari and Krishna, all the rivers reaching Bay of Bengal (NE and SE rivers) drain red loamy and alluvial soils in their upper and lower catchments respectively. The Godavari and Krishna rivers drain black soils in their upper catchment whereas red loamy and alluvial soils in their middle and lower catchments respectively (Geological Survey of India; www.gsi.gov.in). Based on discharge, the monsoonal rivers in this study were divided into two types, namely, the major (>150 $m^3 s^{-1}$) and medium (<150 $m^3 s^{-1}$) rivers.

2.2 Sample collection

Water samples were collected from the freshwater regions of the estuaries ~~rather than from head waters~~ to obtain reliable export fluxes of DIC to the coastal ocean. Samples were collected at 2 to 3 locations to minimize the spatial variability within the freshwater zone of the estuary. Further, to minimize the inter-annual variability in DIC concentrations, sampling was conducted in two different years and the mean was used for export flux estimations. Further, samples were collected in mid-stream of the river using a local mechanized boat to avoid the contamination from river banks.

In-situ measurements and sample collection were conducted in 27 rivers of the Indian subcontinent (Fig. 1) during the SW monsoon season of the years, 2011 and 2014. Surface water samples at each location were collected for phytoplankton biomass (Chl-*a*), DIC and dissolved oxygen (DO). Samples for DIC were collected in air-tight crimp-top glass bottles and added poison (mercuric chloride) to arrest the biological activity. DO analysis was

carried out at a temporary shore laboratory set up for sample processing after the completion of sampling on each day. Water samples were filtered through GF/F (nominal pore size of 0.7µm) under moderate vacuum and stored in liquid nitrogen for Chl-*a* analysis.

2.3. Methods

Temperature and salinity at the sampling locations were measured using a conductivity-temperature-density (CTD) profiling system (Sea Bird Electronics, SBE 19 plus, United States of America). Concentration of DO was determined by a Winkler's method (Carritt and Carpenter, 1966) using an auto titrator (Metrohm, Switzerland) with potentiometric end point detection. The analytical precision of the method was ±0.07% (RSD). Dissolved oxygen saturation is computed following formulations given by Garcia and Gordon (1992). DIC concentrations in water samples were measured at our Institute laboratory using Coulometer (UIC Inc., USA) connected to an automatic sub-sampling system. Based on the repeated analysis of samples and standards, the precision of the method was ±0.02 mg l^{-1}. The certified reference materials (CRM) supplied by Dr. A.G. Dickson, Scripps Institute of Oceanography, USA and internal standards were used to test the accuracy of our DIC measurements and it was found to be within ± 0.2 to 0.3%.. Potetiometric Gran titration method (Metrohm, Switzerland) was used for determination of pH and total alkalinity and followed the standard operating procedures given by Department of Energy (DOE) (1998).

The stable carbon isotopic composition of DIC in the water was measured on Gas Bench coupled with isotope ratio mass spectrometer (EA-IRMS-Delta V, Finnigan,Germany). 50 ml air-tight bottles with rubble septa were filled with 0.5 ml of high purity ortho-phosphoric acid and purged with high purity helium. About 1 ml of water sample

is injected to the bottle and incubated at constant temperature of 50^{o}C for 12 hours. The CO_2 extracted into the head space is injected to the IRMS through gas bench. The results are expressed relative to conventional standards, that is, pee dee belemnite (PDB) limestone for carbon (Coplen, 1996) as δ values, defined as:

$$\delta R = [(Xsample – Xstandard)/Xstandard) \times 10^{3}] ‰$$

where R refers to ^{13}C and X stands for $^{13}C/^{12}C$. The high-purity tank of CO_2 was used as working standard for carbon. These gases were calibrated with IAEA standards. Standard deviation on 20 aliquots of the same sample was lower than 0.05‰ for $\delta^{13}C$. Chlorophyll-*a* (Chl-*a*) on the filter was extracted into di-methyl formamide (DMF) and measured the extract fluorometrically using a spectrofluorophotometer (Varian Eclipse, Varian Electronics., UK) following Suzuki and Ishimaru (1990). Annual mean discharge data of the rivers was taken from Meybeck and Ragu (1995, 1996), Central Water Commission, New Delhi (2006, 2012) and Kumar et al. (2005). Catchment area of the rivers was obtained from Water Resources Information System of India (WRIS, www.india-wris.nrsc.gov.in). Soil organic carbon data was taken from Kishwan et al. (2009) and Sreenivas et al. (2016), and the rainfall data was obtained from Soman and Kumar (1990). Dissolved organic carbon (DOC) data for the Indian rivers was taken from Krishna et al. (2015)

Total export flux of DIC from each river was estimated by multiplying the mean concentrations of DIC at near zero salinity (river end member) with the annual discharge. Spatial variability of DIC concentrations within the river was minimized to a large extent by collecting samples from 2 to 3 locations in each river while the inter-annual variability by collecting samples during discharge periods of two years. However, variability in DIC concentrations within the discharge period results in some uncertainties in our estimations of DIC export fluxes. Time series measurements in the Godavari estuary (our unpublished results) revealed that the variability in DIC concentrations within the discharge period is up to

231 10%. Therefore, the error associated with our DIC flux estimates may be about 10%. DIC
232 flux normalized by catchment area (yield) was calculated by dividing the total DIC export
233 flux of the river by its catchment area.

234 **3. Results**

235 *3.1. Hydrographic characteristics*

236 Surface water temperatures were higher in rivers from the NE and SE regions (mean
237 30.9±1.2^{o}C) than the rivers from SW and NW regions (27.3±1.5^{o}C) of India Dissolved
238 oxygen saturation varied from as low as 63% to as high as 105%, with a mean saturation of
239 90±11%. The rivers from SW region of India recorded more under-saturation of DO (82±7%)
240 than the rivers located in the NE (89±15%), NW (93±3%) and SE (96±11%) regions of India.
241 Chlorophyll-*a* (Chl-*a*) concentrations varied broadly from 0.8 to 7.5 mg m^{-3}, with relatively
242 higher mean concentrations in rivers of the SE region (4.7±2.5 mg m^{-3}) followed by the SW
243 (2.8±0.7 mg m^{-3}) regions of India. On the other hand, relatively low Chl-*a* was observed in
244 the medium (2.6±1.3 mg m^{-3}) than the major estuaries (3.2±2.1 mg m^{-3}).

245 *3.2 DIC concentrations and $\delta^{13}C_{DIC}$*

246 DIC concentrations in the Indian monsoonal rivers widely varied from 3.4
247 (Bharathapuzha) to 73.6 mg l^{-1} (Vellar), with a significant spatial variability (Fig. 3a; Table
248 1). Highest mean DIC concentration was observed in rivers of the SE region (37.4±6.3 mg l^{-1})
249 while the lowest was found in the SW region (5.2±2.1 mg l^{-1}) of India. Intermediate values
250 were found in rivers of the NW (28.4±8.9 mg l^{-1}) and NE (17.1±6.2 mg l^{-1}) regions of India.
251 DIC concentrations were found to be similar in the major (22.7±13.6 mg l^{-1}) and medium
252 (21.1±13.2 mg l^{-1}) rivers (homoscedastic Student's t-test; p=0.76). Mean DIC concentration
253 found in this study (21.4±16.3 mg l^{-1}) is similar to those observed earlier in the major river
254 systems of India (Brahmaputra; Singh et al., 2005) and elsewhere in the world, for example,
255 British rivers (Jarvie et al., 2017) and Swedish rivers (Campeau et al., 2017). However, DIC

256 concentrations in the present study are higher than the global mean DIC (10.3 mg l^{-1},
257 Meybeck and Vorosmarty, 1999) (Table 1), but lower than those reported in the rivers
258 draining into the Gulf of Trieste (N Adriatic; 37-66 mg l^{-1}, Tamse et al., 2014).

259 The $\delta^{13}C_{DIC}$ varied from -13.0 to -1.4‰, with a significant spatial variability (Fig. 3d;
260 Table 1) in the rivers sampled. Relatively depleted $\delta^{13}C_{DIC}$ values were observed in rivers of
261 the NW region (-11.1±2.3‰) while enriched $\delta^{13}C_{DIC}$ was found in rivers of the SE region (-
262 3.5±2.3‰) of India (Fig. 3d). The $\delta^{13}C_{DIC}$ values found in this study are well within the range
263 of values reported earlier in rivers of India (Das et al., 2005) and elsewhere in the world, for
264 example, Swedish streams (-27.6 to -0.6‰; Campeau et al., 2017) and rivers from Italy and
265 Slovenia (-12.8 to -7.7‰, Tamse et al., 2014).

266 *3.3. Export fluxes and yield of DIC*

267 Annual export flux of DIC to the coastal ocean from the individual rivers varied
268 broadly from 0.01 Tg (Chalakudi) to as high as 2.33 Tg (Krishna) (Fig. 3b; Table 1). Among
269 the rivers sampled, rivers of the NE region of India export higher DIC (6.52 Tg yr^{-1}) while
270 the lowest was found from rivers of the SW region (0.24 Tg yr^{-1}) (Table 1). The Indian
271 monsoonal rivers together export about 10.32 Tg yr^{-1} of DIC to the northern Indian Ocean, of
272 which 7.81 Tg (75%) enters into the Bay of Bengal and the remaining into the Arabian Sea
273 (2.51 Tg). The yield of DIC ranged from 2.8 (Bharathapuzha) to 20.7 g m^{-2} yr^{-1} (Baitarani)
274 (3c; Table 1), excluding the exceptionally high yield of 119 g m^{-2} yr^{-1} from Haldia river. The
275 mean yield was found to be more or less similar in rivers from all the four regions of India,
276 i.e, NW (8.4 g m^{-2} yr^{-1}), SW (8.8 g m^{-2} yr^{-1}), SE (6.6 g m^{-2} yr^{-1}) and NE (7.7 g m^{-2} yr^{-1})
277 regions. Despite the export flux of DIC is lowest from rivers of the SW region (0.24 Tg yr^{-1}),
278 interestingly, the yield from rivers of this region is on par with (even slightly higher than) the
279 other Indian monsoonal rivers (Table 1; Fig. 3b&c). Yields of DIC found in this study are
280 similar to those found earlier in rivers elsewhere in the world (Huang et al., 2012).

4. Discussion

4.1 Distribution of DIC in the Indian monsoonal rivers

Distribution of DIC in the Indian monsoonal rivers showed large spatial variability, with the lowest values in rivers from the SW region of India (Fig. 3a). DIC concentrations in rivers are known to be influenced by the intensity of precipitation over the catchment, basin lithology (Giesler et al., 2013; Lofgren et al., 2014), length of the fluvial network (Hotchkiss et al., 2015) and in-stream physical and biological processes (Mook and Tan, 1991; Raymond et al., 2008). The spatial distribution of rainfall over the Indian subcontinent (www.imd.gov.in) shows that the SW region receives the highest annual rainfall (~3000 mm) than the rest of India (Soman and Kumar, 1990).

The intense precipitation over the SW region is expected to cause higher weathering rates and thus higher DIC in rivers (e.g., Gupta et al., 2011), but lower DIC concentrations were found in rivers of this region. It could be due to the influence of dilution because the dense precipitation over the small catchment area (Table 1) might have diluted DIC concentrations in rivers of this region. In order to understand the influence of the density of rainfall on DIC in rivers, we normalized the volume of discharge from the river with its catchment area. The catchment area normalized volume of discharge was found to be much higher in rivers from the SW region (1.71 m^3 m^{-2}) than the rivers from SE (0.17 m^3 m^{-2}), NE (0.6 m^3 m^{-2}) and NW (0.32 m^3 m^{-2}) regions of India. About three times higher catchment area normalized discharge might have diluted DIC concentrations in the rivers of the former region. A strong exponential decrease in DIC concentrations with increasing rainfall over the catchment (r^2= 0.72, $p<0.001$; Fig. 4a) also suggests that DIC concentration in the Indian rivers are strongly influenced by density of precipitation over the catchment.

Rivers of the SW region are relatively small in size, both in terms of catchment area (total catchment area: $20x10^3$ km^2) and the length of the river (mean length: 126 km), than

306 the rivers from other regions (SE, NE and NW) of India (Table 1). Since the contribution of
307 DIC from in-stream processes, such as decomposition of organic matter, has been
308 demonstrated to increase along the course of the fluvial network (Hotchkiss et al., 2015),
309 possibly due to increase in the residence time of water (Catalan et al., 2016), the lowest DIC
310 concentrations found in rivers from the SW region may also, at least partly, be due to their
311 small size. Fairly good positive correlation between DIC concentrations and length of the
312 rivers (r^2=0.38, p<0.01; Fig. 4b) also support this argument.

313 The major physical and biological processes controlling DIC concentrations in rivers
314 are the exchange of CO_2 with the atmosphere, ~~ic CO_2,~~ autotrophic removal and heterotrophic
315 addition of DIC. Since the Indian monsoonal estuaries have been reported to be a source of
316 CO_2 to the atmosphere during the discharge period due to heterotrophic decomposition of
317 organic matter (Sarma et al., 2001, 2011, 2012; Gupta et al., 2008, 2009; Bhavya et al.,
318 2018), the DIC input from the dissolution of atmospheric CO_2 may be unlikely. On the other
319 hand, organic matter decomposition is expected to add significant amount of DIC as
320 enhanced bacterial respiration rates were reported during this period (Sarma et al., 2011;
321 2012). In contrast, significant negative correlation between chlorophyll-*a* and DIC (r^2=-0.44,
322 p<0.01; Fig. 4c), except few SE rivers where elevated phytoplankton biomass (Chl-a: >5 mg
323 m^{-3}) was recorded, suggesting that autotrophic removal of DIC is also significant in the
324 Indian monsoonal rivers during the study period. A significant positive relationship was
325 observed between the $\delta^{13}C_{DIC}$ and Chl-a (r^2=0.49; p<0.01; Fig. 4d), supporting this argument
326 because preferential uptake of ^{12}C than ^{13}C during photosynthesis leaves the residual DIC
327 enriched in ^{13}C. On the other hand, $\delta^{13}C_{DIC}$ showed significant positive correlation with DO
328 saturation (r^2=0.50, p<0.01; Fig. 4e) (depleted $\delta^{13}C_{DIC}$ values at more under saturation of DO)
329 and DOC concentrations (r^2=0.43, p<0.01; Fig. 4f) as was observed in the Xi river (Zou et al.,
330 2016). Altogether, enriched $\delta^{13}C_{DIC}$ are associated with higher DOC, less under saturation of

331 DO and higher phytoplankton biomass (Chl-a) while the depleted $\delta^{13}C_{DIC}$ are associated more
332 under saturation of DO and less DOC. This suggests that both autotrophic removal and
333 heterotrophic addition control DIC in the Indian rivers during the discharge period, with a
334 considerable spatial variability. However, influence of these processes on DIC
335 concentrations is difficult to separate with this bulk $\delta^{13}C_{DIC}$ data set, as the $\delta^{13}C_{DIC}$ in rivers is
336 also influenced by pollution, catchment lithology and outgassing of CO_2 (Shin et al., 2011;
337 Brunet et al., 2005; Bou~~v~~ill~~i~~on et al., 2009; Zeng et al., 2011; Tamooh et al., 2013).
338 Excluding Sabarmati and Mahisagar rivers, DIC concentrations showed fairly good linear
339 relationship with population density over the catchment of the river (r^2=0.41, p<0.01; Fig.
340 4g), suggesting that considerable influence of pollution from the mega cities and industries on
341 DIC in the Indian rivers.

342 Spatial distribution of soils shows that rivers of the NW region of India and upper
343 reaches of Krishna and Godavari rivers drain the lime-rich black soils (Fig. 1) while rivers
344 from the SW region drain red loamy soils. Whereas, the east-flowing rivers drain the lime-
345 poor red sandy soils in the upper but lime-rich alluvial soils in the lower reaches (Fig.1).
346 Lateritic soils, which are poor in lime and silicate, occupied the catchment of the rivers in the
347 SW region of India. Relatively lower chemical weathering rates of the lateritic than the non-
348 lateritic soils could be one of the reasons for the observed lower DIC concentration the rivers
349 from SW region of India. A significant positive correlation was found between total
350 alkalinity (TA) and $\delta^{13}C_{DIC}$ (r^2=0.52; p<0.01; Fig. 4h), suggesting that significant contribution
351 of DIC is from weathering of carbonate minerals in the catchment. Though the higher
352 chemical weathering rates were reported for the Deccan Trap basalts (Das et al., 2005;
353 Singh et al., 2005), which occupied the catchments of rivers of the NW region of India and
354 upper reaches of Godavari and Krishna, higher DIC concentrations were also observed in

rivers draining over the metamorphic rocks. This suggests that the influences of factors other than bedrock are also significant on the concentrations of DIC in the Indian rivers.

4.2 Major sources of DIC in the Indian monsoonal rivers

Though, the $\delta^{13}C_{DIC}$ is a promising tool to decipher the sources of DIC, its interpretation for source material identification in rivers is still challenging because multiple physical and biological processes within the rivers significantly alter the $\delta^{13}C$ of DIC source. The influence of major in-stream processes on the $\delta^{13}C_{DIC}$ must be separated before interpreting the results for major sources of DIC, failing which leads to erroneous conclusions. In order to identify and separate DIC sources, we used here two different graphical mixing model techniques, Keeling plot (Keeling, 1958; Pataki et al., 2003) and Miller-Tans plots (Miller and Tans, 2003). These models approximate the hypothetical $\delta^{13}C$ of source material as an intercept (in Keeling plot) and slope (in Miller-Tans plot) of the least square linear regression equations (Pataki et al., 2003; Campeau et al., 2017). The deviations from the approximated $\delta^{13}C$ of source can be interpreted ~~to~~ as the influence of in-stream processes. Further, we approximated the $\delta^{13}C$ of CO_2 using a set of enrichment factors of isotopic fractionation across the carbonate species (Zhang et al., 1995) in order to filter the impact of DIC speciation and pH on the bulk $\delta^{13}C_{DIC}$ values. This approach has already been used by Quay et al. (1992), Mayorga et al. (2005) and recently by Campeau et al. (2017).

Significant negative relationships were observed in both Keeling plot ($\delta^{13}C_{DIC}$ as a function of 1/DIC; Fig. 5a) and Miller-Tans plot ($\delta^{13}C_{DIC}$ x DIC as a function of DIC; Fig. 5b) (r^2=0.61, p<0.01 and r^2=0.72, p<0.01 respectively) of DIC in the Indian rivers, except the rivers draining the Deccan Trap basalts. Both graphical mixing models, Keeling and Muller-Tans plots, approximated the similar $\delta^{13}C$ of source material (-3.0‰ and -2.0‰ respectively; Fig. 5a&b), suggesting that weathering of carbonate minerals is the predominant source of

DIC in the Indian monsoonal rivers rather than biogenic soil CO_2. Calculated $\delta^{13}C$ of CO_2 ranged from -21.5 to -9.6‰ in the Indian rivers with a mean value of -13.0±2.7‰. Calculated $\delta^{13}C$ of CO_2 is linearly correlated with the measured $\delta^{13}C_{DIC,}$ but correlation coefficient (r^2) is only 0.51 (Fig. 5c), suggesting that significant spatial variability in the influence of in-stream processes on the $\delta^{13}C_{DIC.}$ The Miller-Tans plot of CO_2 ($\delta^{13}C$-CO_2 x CO_2 as a function of CO_2) showed highly significant linear regression model with a slope of -10.7‰ (r^2=0.97; $p<0.001$; Fig. 5d). These results indicated that chemical weathering of carbonate and silicate minerals by soil CO_2 (-10 to -9‰) is the major source of DIC in the Indian rivers. ~~is largely~~ contributed by ~~chemical weathering of carbonate and silicate minerals by soil CO_2 (-10 to -9‰)~~. Deviations of the measured $\delta^{13}C_{DIC}$ (-13.0 to -1.4‰) from that of the approximated $\delta^{13}C$ of DIC source (-3.0 to -2.0‰) and $\delta^{13}C$ of CO_2 (-10.7‰) could be due to the influence of in-stream process. In more than 75% of the Indian rivers sampld, the deviation from the $\delta^{13}C$ of DIC source is towards negative side (depletion) ($\delta^{13}C_{DIC}$ < -3.0‰), suggesting that heterotrophic decomposition of organic matter is the dominant process controlling DIC in these rivers. While, no (or very little) deviation was observed only in rivers from the SE region of India (mean $\delta^{13}C_{DIC}$: -3.1‰) could be due to the competition between autotrophy, degassing and heterotrophy as these processes influences the $\delta^{13}C_{DIC}$ in opposite directions (Fig. 2); the former two processes causes enrichment while the latter depletes $\delta^{13}C_{DIC}$. Relatively higher phytoplankton biomass (mean Chl-a: 4.6 mg m^{-3}) and less under-saturation of DO (98.7%) was observed in these rivers compared to the mean of the rest of the Indian rivers (2.4 mg m^{-3} and 87.5% respectively), suggesting that autotrophy is one of the dominant processes controlling DIC in rivers from the SE region of India. Total number of dams on the rivers from this (SE) region (mean 155, Table 1) is not significantly higher from that of the mean of total number of dams on the Indian rivers sampled (mean 135) , suggesting that

degassing due to storage of water may not be the dominant process responsible for enrichment in $\delta^{13}C_{DIC}$ of these rivers.

4.3 Total DIC export by the Indian monsoonal rivers to the north Indian Ocean

Indian monsoonal rivers annually export ~10.3 Tg of DIC to the north Indian Ocean. Nearly three fourth of this amount (7.8 Tg) reaches to the Bay of Bengal while ~~the remaining into~~ the Arabian Sea receives only one fourth (2.5 Tg). This is consistent with the higher magnitude of freshwater discharge to the Bay of Bengal (378 $km^3\ yr^{-1}$) from the catchment area of about $970x10^3\ km^2$ than the Arabian Sea (122 $km^3\ yr^{-1}$ from the catchment area of $244x10^3\ km^2$). The total DIC export by the Indian monsoonal rivers (10.3 Tg yr^{-1}) is ~~far less~~lower than the DIC export by the American (61.4 Tg yr^{-1}) and African (17.7 Tg yr^{-1}) rivers and major rivers draining to the tropical Atlantic from South America and Africa (53 Tg yr^{-1}, Araujo et al. 2014). It is mainly due to the fact that freshwater discharge from the Indian monsoonal rivers is very low (~500 $km^3\ yr^{-1}$) compared to the American (11,799 $km^3\ yr^{-1}$) and African (3,786 $km^3\ yr^{-1}$) rivers. However, the Indian monsoonal rivers are exporting disproportionately higher DIC because they account for only 1.3% of the global river discharge but export 2.5% of the global riverine DIC export to the oceans (400 Tg yr^{-1}). Though American and African rivers account for 30% and 10% of the global river discharge, they export only 15% and 4.4% of global riverine DIC to oceans, respectively. Disproportinately higher DIC flux from the Indian rivers could be due to relativley higher weathering rates of silicate and carbonate minerals in their drainage basins (Das et al., 2005; Gurumurty et al., 2012; Pattanaik et al., 2013). Higher DIC fluxes from the tropical regions are mainly attributed to the favourable climatic conditions, lithology and land use cover (Huang et al., 2012) of this region for higher dissolution.

Krishna et al. (2015) reported that Indian monsoonal rivers export 2.32 Tg yr^{-1} of dissolved organic carbon (DOC) to the north Indian Ocean. The total fluvial dissolved carbon

429 flux (DIC+DOC) would be 12.6 Tg yr^{-1} in which DIC flux contributed up to ~81%. The
430 predominance of DIC has also been found in rivers elsewhere in the world, for example, the
431 British rivers (Jarvie et al., 2017) and high altitude Swedish rivers (Campeau et al., 2017).
432 Since the catchment area of the Indian monsoonal rivers ranged widely from as low as $1x10^3$
433 km^2 to as high as $313x10^3$ km^2, the export fluxes of DIC were normalized with the catchment
434 area of the river (yield) in order to examine various factors controlling the DIC export to the
435 north Indian Ocean.

436 **4.4 Yield of DIC from the Indian monsoonal rivers**

437 The yield of DIC found in this study (mean 8.7±5.2 g m^{-2} yr^{-1}) is close to those found
438 in rivers from the tropical region of Asia, but significantly higher than those reported from
439 tropical region of the American and African continents (Huang et al., 2012). The yield was
440 highest (8.8±5.6 g m^{-2} yr^{-1}) in rivers from the SW region of India, despite they export
441 relatively lower DIC (0.3 Tg yr^{-1}) due to their low volume of discharge (46 km^3 yr^{-1}) and
442 relatively smaller catchment ($20x10^3$ km^2) than the rivers from SE, NE and NW regions of
443 India (Table 1. DIC yield showed a significant positive correlation with the volume of
444 discharge (r^2=0.67, $p<0.001$; Fig. 6a) in medium rivers and no such relationship was found in
445 the major rivers. Significant negative relationship was observed between DIC yield and
446 catchment area of river (r^2 = -0.49, $p<0.001$; Fig. 6b and r^2 = -0.43, $p<0.001$; Fig. 6c for
447 medium and major rivers respectively), suggesting the smaller rivers export more DIC per
448 unit area of catchment compared to the major river systems, and thus inclusion of DIC data
449 from medium rivers in the world significantly alters the global estimations of DIC A fairly
450 good linear relationship between the yield of DIC and the intensity of precipitation (r^2=0.43,
451 $p<0.01$ Fig. 6d) was observed only in the rivers which receives >2000mm of annual mean
452 precipitation. Higher precipitation over the catchment increases the yield of DIC because the
453 dense precipitation enhances the extraction of DIC from soils and rocks in their catchment

Therefore, high precipitation (~3000 mm) over the small catchment ($20x10^3$ km^2) could have increased DIC yield from the rivers of SW region of India.

Sreenivas et al. (2016) and Krishwan et al. (2009) found that the soil organic and inorganic carbon contents in the surface (100cm) soils in the catchment of rivers in the SW region were higher and lower, respectively, than the catchments of the rivers from SE, SW and NE region of India. Decomposition of soil organic matter releases excess CO_2 and, the increase in soil CO_2 leads to the formation of acidic conditions in soils. This would increase the DIC yield by more dissolution of soil carbonates and chemical weathering of carbonate and silicate rocks (Zou et al., 2016). A significant linear correlation was found between soil organic carbon content and DIC yield in this study (r^2=0.65, $p<0.001$; Fig. 6e), suggesting that higher soil organic carbon in the catchment of the rivers from SW region could have elevated the yield of DIC from rivers of this region. The basin scale studies are, however, required for comprehensive understanding of the influence of environmental and anthropogenic factors on export fluxes and yield of DIC from the Indian monsoonal rivers.

5. Summary

In order to examine the spatial variability in the sources and distribution of dissolved inorganic carbon (DIC) in the Indian monsoonal rivers, and to estimate their export fluxes of DIC to the north Indian Ocean, we sampled a total of 27 major and medium rivers during wet period. An order of magnitude variability was found in DIC concentrations among the rivers sampled (3.4 - 73.6 mg l^{-1}), with a lower mean concentration of 6.6±2.1 mg l^{-1} in rivers located in the SW region of India. It is attributed to significant spatial variability in the size of rivers, precipitation pattern, pollution and lithology in their catchments. The approximated $\delta^{13}C$ of DIC source from the Keeling and Miller-Tans plots (-2.0 and -3.0‰ respectively) and, the calculated $\delta^{13}C$ of CO_2 ~~which filters the influence of pH and DIC speciation,~~ suggested that DIC in the Indian rivers is mainly originated from chemical weathering of

carbonate minerals, but largely affected by autotrophic production in rivers from the southeast region of India and heterotrophic decomposition of organic matter in rivers from other regions of India. Indian monsoonal rivers together export ~10.3 Tg yr^{-1} of DIC to the north Indian Ocean, of which 7.8 Tg yr^{-1} enters in to the Bay of Bengal while the Arabian Sea receives only 2.5 Tg yr^{-1}. It is mainly attributed to the volume of river discharge as the former receives ~378 km^3 yr^{-1} while the latter receives only 122 km^3 yr^{-1} from the Indian monsoonal rivers. Dense rainfall and higher soil organic carbon content in the catchment of rivers from the SW region than in the catchment of the other Indian rivers resulted in highest yield of DIC from the former than the latter.

6. Acknowledgements

We would like to thank the Director, CSIR - National Institute of Oceanography (NIO), Goa, and the Scientist-In-Charge, NIO-Regional Centre, Visakhapatnam for their kind support and encouragement. We also acknowledge Dr. M. Dileep Kumar, NIO, Goa for his guidance and encouragement. The work is part of the Council of Scientific and Industrial Research (CSIR), funded research project. Figure captions

Figure 1: Map showing the study region. Rivers sampled in this study were indicated by solid black line. Distribution of soils in catchments of the Indian monsoonal rivers sampled was also shown. Rivers draining the four regions, i.e., northwest (NW), southwest (SW), southeast (SE) and northeast (NE) were shown by solid black arrows.

Figure 2: Schematic diagram showing the typical range of ~~the~~ $\delta^{13}C$ of different sources of ~~end members of~~ dissolved inorganic carbon (DIC) ~~sources~~in rivers. Various major processes influencing the $\delta^{13}C$ of DIC ($\delta^{13}C_{DIC}$) within the rivers were also shown. Hollow b~~B~~lack arrows (- ⇦ and ⇨ –) indicates the direction of change in $\delta^{13}C_{DIC}$ due to the influences different in-stream process mentioned against arrows.

Figure 3: Spatial variability in concentration (mg l^{-1}; 3a), export flux (Tg yr^{-1}; 3b) and yield (g m^{-2} yr^{-1}; 3c) of dissolved inorganic carbon (DIC) and its stable isotopes ($\delta^{13}C_{DIC}$, 3d) in the Indian monsoonal rivers studied. Rivers geographically located in the northwest (NW), southwest (SW), southeast (SE) and northeast (NE) regions of India were also shown. Rivers draining into the Bay of Bengal (east-flowing rivers) were shown by gray shade while rivers draining into the Arabian Sea (west-flowing) were shown by no shade.

Figure 4: (a) Exponential decrease and (b) linear increase of dissolved inorganic carbon (DIC) concentrations with increasing the rainfall over the catchment and length of the river respectively. (c) Inverse and (d) linear relationships of chlorophyll-a (Chl-a) with concentrations and $\delta^{13}C$ of DIC respectively. Significant linear relationships of $\delta^{13}C$ of DIC with (e) dissolved oxygen (DO) saturation and (f) dissolved organic carbon (DOC) concentration. Linear relationships observed between (g) DIC concentrations and population density in the catchment and (h) total alkalinity and $\delta^{13}C$ of DIC in the Indian monsoonal rivers during the study period. Ovals with dashed line indicate the~~at~~ outliers which were not included in the regression equations. Rivers of the northwest region of India showed linear relationships as shown by the other Indian rivers but with a different slope (Fig. f-h)

Figure 5: Least square linear regression models of (a) $\delta^{13}C_{DIC}$ as a function of 1/DIC (Keeling plot) and (b) $\delta^{13}C_{DIC}$xDIC as a function of DIC concentrations (Millerte-Tans plot) in the Indian monsoonal rivers. (c) Linear relationship between calculated $\delta^{13}C$ of CO_2 and the measured $\delta^{13}C_{DIC}$ and (d) Miller-Tans linear regression model of $\delta^{13}C$-CO_2 x CO_2 as a function of CO_2 concentration in the Indian monsoonal rivers.

Figure 6: Significant relationships of dissolved inorganic carbon (DIC) yield with (a) river discharge in medium estuaries, (b) catchment areas of the medium rivers, (c) catchment areas of the major rivers, (d) rainfall over the catchment of all the rivers sampled and (e) soil

organic carbon (OC) content in catchments of the Indian monsoonal rivers studied. Since the data on soil OC is not available for each watershed (e) was plotted using the available soil OC data on regional scale (NW, SW, SE and NE regions of India), Hence, it contains only four points.

Table captions

Table 1: Catchment area, discharge, length and elevation of each river and, annual mean rainfall, number of dams and population density in each watershed of the Indian monsoonal rivers sampled. Concentrations, export fluxes and yields of dissolved inorganic carbon (DIC) and its stable isotopes ($\delta^{13}C_{DIC}$) of Indian rivers were given. Measured pH and calculated $\delta^{13}C$ of CO_2 from isotopic fractionation factors across DIC speciation were also provided. Rivers located in the northern region (north of 16°N) of India were shown by the shaded (grey) area. Of these rivers, Mahisagar, Sabarmati, Tapti and Narmada are located in the northwestern (NW) region whereas, rivers from Godavari to Hyadri are located in the northeastern (NE) region of India.
