

1 **REPLY TO REVIEWER #1**

2 We thank the reviewers and the associate editor for their constructive comments. We have
3 addressed the comments by reviewer #1 (as detailed below) and have revised the manuscript
4 accordingly. Please note that page and line numbers in the reviewer's comments refer to the
5 original manuscript while our references to page and line numbers refer to the revised manuscript.

6 Specific comments: Page 3, Lines 49-52: Hill et al., 2005 → Hill and Cota, 2005, Arrigo et al.,
7 2015 → Arrigo and van Dijkend, 2015, Bélanger et al., 2013 → Bélanger et al., 2008?, Wassmann
8 and Slagstad, 2011 → Wassmann et al., 2011. Please check references throughout the text!!

9 We thank the reviewer for pointing out the mistakes in reference list. We have thoroughly checked
10 and revised.

11 Page 3, Line 60: McLaughlin and Carmack, 2010 → McLaughlin et al., 2010

12 Corrected

13 Page 4, Line 70: Bélanger et al., 2013 → check the reference!

14 This reference is added in the reference list of the revised manuscript.

15 Page 4, Line 74: Vancoppenolle et al., 2013 → this citation is no in reference list!

16 This reference is added in the reference list of the revised manuscript.

17 Page 5, Line 94: Does your measured carbon uptake correspond to NPP or primary production?
18 You need consistency for that throughout the text. Otherwise, you need to define NPP.

19 The present study addressed only small phytoplankton uptake rates measured on the basis of a 4hrs
20 *in situ* incubation experiments. Hence, the data do not represent net primary production. To make
21 sure the consistency we removed the term net primary production from the manuscript.

22 Page 6, Line 132: "The chlorophyll (chl) samples" → Does it mean the chlorophyll a? Or does it
23 contain chlorophyll a, b, and c? Kind of confused in the text!

24 We used Chl *a* for the present study. We have replaced "Chl" with "Chl *a*" in the revised
25 manuscript.

26 Pages 6-7: In materials and methods section, there is no description for how to measure water
27 temperature and salinity, although water temperature and salinity data are used in Table 1 and

28 described in the text. Please describe a detail method for the water temperature and salinity
29 measurement!

30 The temperature and salinity were measured using a Seabird SBE9plus CTD (conductivity-
31 temperature-depth tool) equipped with dual temperature (SBE3) and conductivity (SBE4) sensors.
32 The information regarding temperature and salinity measurements has been added to the revised
33 manuscript.

34 Page 7, Line 134: Lee et al.,2005 → Lee and Whitledge, 2005

35 Corrected

36 Page 7, Line 149: "Niskin bottles attached to CTD" → CTD spell out!

37 CTD stands for Conductance Temperature Depth device. We have added the full term in the
38 revised manuscript.

39 Page 8, Line 165: Slawyk et al. 1977 → Slawyk et al. (1977)

40 Corrected

41 Page 9, Lines 180-184: No unit for the salinity!

42 Salinity is measured in Practical Salinity Unit (PSU). Usually it is not mentioned particularly.
43 However, we added the unit of salinity in the revised manuscript as per the reviewer's suggestion.

44 Page 9, Line 182: When I read this sentence, I thought that you investigated for a late summer in
45 2013.

46 We agree with the reviewer and changed it in the revised manuscript.

47 Page 9, Lines 189-191: I think authors may need to redraw figure 2 because I don't know whether
48 the subsurface chlorophyll maximum actually exists in this figure. I think it is only the results of
49 some stations.

50

51 Figure 2. does not contain any chlorophyll data. We have plotted the depth profiles of C, NO_3^- ,
52 and NH_4^+ uptake rates and explained about the subsurface maxima of uptake rates. We also revised
53 the two sentences (190-192) as given to make the idea more clear.

54 "Fig. 2 shows the depth profiles C, NO_3^- , and NH_4^+ uptake rates in the Laptev, Kara, and East
55 Siberian seas. Only a few stations showed significant subsurface maxima for the C, NO_3^- , and
56 NH_4^+ uptake rates during the present study where the rest of them exhibited no significant variation
57 throughout euphotic zone".

58 Page 9, Line 193: "Fig. 3 & 4" → Figs.

59 Corrected

60 Page 10, Line 211: Parkinson, 2002 → this citation is no in reference list!

61 Reference is added in the revised manuscript.

62 Page 11, Line 227: "Table 2, Fig. 3 & 4" → Figs.

63 Corrected

64 Page 11, Line 239: Kirk, 1983 → this citation is no in reference list!

65 Added to the reference list.

66 Page 11, Line 240: Shiklomanov, 2000 → Shiklomano et al., 2000

67 We have checked the reference, however, we found that Shiklomanov, 2000 is the correct version.

68 Page 12, Lines 252-258: "The depth-integrated $\text{NO}_2^- + \text{NO}_3^-$ concentrations varied between" →

69 ". . . concentrations in the euphotic zone varied. . . ." You do not show euphotic zone depth. Add

70 euphotic zone depth in Table 1. If the difference in the depth of euphotic is large, the result may

71 be influenced in nutrients budget. Also, I think that the meaning of "high concentrations of

72 $\text{NO}_3^- + \text{NO}_2^-$ and phosphate" are ranked based on only nitrogen data and mentioned stations are not

73 special compared to other stations.

74 We agree to the reviewer's opinion regarding the influence of euphotic depth on depth integrated

75 nutrient budget. We have added euphotic depth details in Table 1. The euphotic depths observed

76 are different in almost all of the stations ranging from 33 to 76 m. However, the data from our

77 present study did not show any dependency of depth integrated nutrient budget with euphotic depth.

78 For example, AF019, Af080, and AF095 stations have deeper euphotic zone, however; they are

79 not having depth integrated $\text{NO}_2^- + \text{NO}_3^-$ concentrations close to the highest values obtained at

80 AF068, AF071, and AF005 which are having relatively shallower euphotic depths. The depth

81 integrated P values also showed higher values at stations (AF019, AF068, AF100, AF080, AF095,

82 and AF091) with both deeper and shallower euphotic depths. Based these information we could

83 not derive any correlation between euphotic depths and nutrient budget. We have added one

84 paragraph to explain these findings in the revised manuscripts (lines: 303-312).

85 Page 12, Line 262: this the stations → what stations?

86 We have corrected the sentence in the revised manuscript as “In reference to the stations (AF005,
87 AF068, and AF071 in the Laptev Sea and AF100 in the Kara Sea) nearby the river inlets were
88 observed with relatively higher nutrient concentrations (Table 1).”

89 Page 12, Line 257: “Table 1, Fig. 3 & 4” → Figs.

90 Corrected.

91 Page 13, Line 268: “higher than those of present study area” → You do not show daily data for
92 carbon uptake rates! Add your data based on daily carbon uptake rates!

93 The reference which we used was for total primary production. So we revised that sentence with
94 small phytoplankton primary production data by Lee et al. (2017a). The revised sentence is as
95 follows. “In agreement to this, the small C uptake rates reported from the Chukchi Sea (58.6–194
96 $\text{mg C m}^{-1} \text{d}^{-1}$; average = $127 \pm 55.2 \text{ mg C m}^{-1} \text{d}^{-1}$); Lee et al., 2017a) was relatively higher than those
97 of present study ($5.86\text{-}191 \text{ mg C m}^{-2} \text{d}^{-1}$; average = 37.7 ± 41.6)”.

98 Page 13, Line 272: Glibert et al., 2011 → this citation is no in reference list!

99 Reference is added in the revised manuscript.

100 Page 13, Line 288: It is necessary to investigate whether there is a relationship between SST and
101 small phytoplankton uptake rate. You are dealing with an entirely different ecosystem as you
102 mentioned.

103 We appreciate the reviewer’s opinion. The relationship of small phytoplankton DIN and C uptake
104 rates with SST was checked already. However, a significant relationship was not observed. It can
105 be possibly due to the narrow range of SST variation among the stations and also due to co-
106 influence of multiple environmental factors.

107 Page 14, Lines 290-293: “However, Fig. 5 show a weak,....” → Authors just stated that possibility
108 of small phytoplankton efficiency to peak at nutrient stoichiometry close to Redfield’s ratio. In my
109 opinion, the DIN: P ratio of less than 16 means mainly nitrogen limitation in ocean. If DIN: P is
110 the degree of nitrogen limitation, it can be interpreted that small phytoplankton is just
111 advantageous to survive better than large. I wonder why the contribution of small phytoplankton
112 is below 50% despite of the nitrogen limitation. Why did this happen? I guess that DIN:P ratios

113 below 8 seem to affect the rate of phytoplankton uptake regardless of size based on limited data in
114 this study.

115 We agree with the reviewer's comment partially. It is possible that nutrient limitation can affect
116 the small phytoplankton potential to assimilate C and N. However, from our study we could
117 observe that the contributions were higher as 80% as well as lower as 25% at DIN:P below 8:1.
118 However, the average small phytoplankton contributions are above the global average. And also,
119 the results from the present study cannot claim that the lower DIN:P is the reason for lower
120 contributions of small phytoplankton to the total primary production. We have explained it in the
121 revised manuscript. Lines: 331-339 and 445-458

122 Page 14, Lines 299-300: "between small phytoplankton uptake are DIN:P" → "and" instead of "are"
123 Corrected as per the reviewer's suggestion.

124 Page 15, Line 316: "Fig. 6 & 7" → Figs.

125 Corrected.

126 Page 15, Line 323: Glibert et al., 1982 → Glibert, 1982

127 Corrected.

128 Page 15, Line 314: " the bottom water. . . . (1000-1700 hours) turnover times compared to" →
129 ". . . turnover times for NH_4^+ substrate. . ." And what does mean bottom depth? Is it correspond to
130 1% light depth? Define the bottom depth in euphotic zone!

131 Checked and corrected as follows, Page 17: lines: 361-364

132 "Fig. 7 shows that turnover times for NH_4^+ substrate (within 500 hours) in the surface waters is
133 longer, however; relatively faster than NO_3^- in upper layers of euphotic zone in almost all the
134 stations in the Arctic Ocean. However, the bottom waters of euphotic zone showed relatively
135 longer (1000-1700 hours) turnover times for NH_4^+ substrate compared to the surface waters."-
136 Lines 368-373

137 Page 15, Line 316: "both NO_3^- and NH_4^+ substrates" → at surface water???? Or throughout the
138 euphotic zone?

139 Yes. Station AF044 showed consistently higher turnover times for both NH_4^+ and NO_3^- in the
140 surface waters. We have revised the sentence as follows "The sampling location in East Siberian

141 Sea (AF044) was observed with relatively longer turnover times for both NO_3^- and NH_4^+ substrates
142 at the surface layers (Figs. 6 & 7) possibly due to the lower uptakes rates over there”.

143 Page 16, Line 339: “quantum efficiency/yield” → quantum efficiency (or quantum yield)

144 By “/” we meant “or” here. To avoid the confusion we replaced “efficiency/yield” by only “yield”
145 in the revised manuscript. We also modified the sentence as “The quantum yield for the present
146 study is defined as the uptakes of DIN ($\text{NO}_3^- + \text{NH}_4^+$ uptake rates) and C by unit small
147 phytoplankton Chl *a* fraction which is obtained by dividing uptake rates by Chl *a* concentrations”.

148 Page 16, Line 341: “in Fig. 8 and 9” → Figs.

149 Corrected.

150 Page 16, Lines 355-356: Wassmann and Slagstad, 2011 → Wassmann et al., 2011, Tremblay et
151 al., 2002 → this citation is no in reference list! Please check the reference!

152 Corrected.

153 Page 17, Line 374: Legendre et al. (1993) → 1992?, check the reference! Please, double check and
154 correct them, if needed.

155 Checked and corrected as per the reviewer’s suggestion. It is Legendre et al., 1992.

156 Page 17, Line 375: “large phytoplankton cells (45 μm)” → check the cell size. I think it probably
157 means > 5 μm .

158 We apologize for the typo mistake. We have corrected it to >5 μm in the revised manuscript.

159 Page 29, Fig. 2: Rephrase legend for Fig. 2

160 Corrected.

161

162

163

164

165

166

167

168 **REPLY TO REVIEWER #2**

169

170 We thank the reviewers and the associate editor for their constructive comments. We have
171 addressed the comments by reviewer #2 (as detailed below) and have revised the manuscript
172 accordingly. Please note that page and line numbers in the reviewer's comments refer to the
173 original manuscript while our references to page and line numbers refer to the revised manuscript.

174 Some missing references and incorrect ones, e.g., Hill and Cota, 2005, Arrigo et al., 2015,
175 McLaughlin and Carmack, 2010, and more. Authors need to check the references throughout the
176 text.

177 We have checked the references thoroughly and edited as per the reviewer's suggestions.

178 The list of new references are given below,

219 Line 97, The major rivers flows in to the Arctic.. Change with flow into the Arctic.

220 Changed as per the reviewer’s suggestion.

221 Line 109, ..a first.. Change with the first.

222 Changed as per the reviewer’s suggestion.

223 No detail description for the measurements for water temperature and salinity in materials and
224 methods.

225 We have added the information regarding temperature and salinity measurement in the revised
226 manuscript as follows. “The temperature and salinity were measured using a Seabird SBE9plus
227 CTD (conductivity-temperature-depth tool) equipped with dual temperature (SBE3) and
228 conductivity (SBE4) sensors”. Lines 129-130

229 Line 132, The chlorophyll (chl) samples... chlorophyll a? or chlorophyll a, b, and c?

230 We have used Chl *a* for the present study and the manuscript is revised by replacing Chl with Chl
231 *a*?

232 Line 140, C and N uptake rates.. C and DIN uptake rates?

233 By “N” we meant “DIN”. To avoid confusion we have replaced “N” with “DIN” in the revised
234 manuscript.

235 Line 151, light filters.. What kind of light filters?

236 We have used neutral density light filters (LEE filters) to cover the polycarbonate sample bottles.
237 The details have added in the revised manuscript. Line 154
238 Line 165, the methods Slawyk et al., 1977.. Check the sentence!
239 We have revised the sentence as per the reviewer's suggestion. Lines 175-178
240 Line 191, a subsurface maxima like most of global ocean.. You need add some related references
241 for that!
242 Since we did not get references for depth profiles of small phytoplankton uptake rates, we revised
243 the sentence without reference. We reframed the sentence to avoid confusion as follows,
244 "Fig. 2 shows the depth profiles C, NO_3^- , and NH_4^+ uptake rates per hour in the Laptev, Kara, and
245 East Siberian seas. Only a few stations showed significant subsurface maxima for the C, NO_3^- , and
246 NH_4^+ uptake rates during the present study where the rest of them exhibited no significant variation
247 throughout euphotic zone". Lines 193-197
248 -Line 194, The depth integrated.. Make a consistency with depth integrated inline 192
249 Replaced "depth integrated" with "depth-integrated" throughout the manuscript as per the
250 reviewer's suggestion.
251 Line 197, the maximum small plankton. . . small phytoplankton?
252 It is "small phytoplankton". The correction has been done in the revised manuscript.
253 Line 197-198, How about any explanation for the maximum uptake rates at AF09?
254 The exceptionally high uptake rates for C, NO_3^- , and NH_4^+ obtained at station AF019 is indeed
255 very interesting. We observed very high particulate organic carbon as well as nitrogen
256 concentration and specific small phytoplankton uptake rates compared to other stations. However,
257 chlorophyll concentrations for the small phytoplankton community did not show such higher
258 values when compared to other stations. Based on the background data obtained during the present

259 study could not give a possible reason to the high uptake rates. We assume that the higher
260 metabolic rates can be due to presence of different autotrophic communities which are different
261 from other sampling locations. Unfortunately, we could not obtain species identification data
262 during the present study. Lines 205-213.

263 Line 219-220, any related reference?

264 As per the reviewer's suggestion we have added references for the contribution of ice algae to the
265 primary production. Clasby et al., 1973 and Horner and Schrader, 1982

266 Line 227-228, higher C and DIN uptake rates of what? Small phytoplankton or total phytoplankton?

267 We meant small phytoplankton uptake rates here. We apologize for the confusion.

268 -Line 231, lower C and DIN uptake rates of what? Small phytoplankton or total phytoplankton?

269 ⇒ very confused!!

270 We meant small phytoplankton uptake rates here. The manuscript is revised accordingly to remove
271 the ambiguities regarding small and total uptake rates. We attempted to compare with the small
272 phytoplankton uptake rates obtained from various regions in the revised manuscript.

273 Line 236, metabolic activities of phytoplankton. Small phytoplankton?

274 Yes. It is small phytoplankton. We have edited it in the revised manuscript.

275 -Line 237, Not much discussion for small phytoplankton primary production in 3.4 section!! You
276 need to focus more on small phytoplankton primary production.

277 We have attempted to explain more about the small phytoplankton uptake mechanism and
278 influence of nutrient concentrations on the small cells. Since there are not many experiments
279 conducted on small phytoplankton uptake rates, particularly from polar oceans, the comparative
280 analysis is relatively difficult. However, we attempted to give a better explanations in the revised
281 manuscript using the available resources. Lines 257-276 and 331-339.

282 -Line 253-254, make a same digit for concentrations.

283 We would like to keep 3 significant digits for the nutrients. In that case 22.3 and 189 are having
284 same significant digits that is 3. We believe that this representation is statistically correct. With
285 reviewer's permission we would like to keep the data same as it is.

286 -Line 258, check the sentence!

287 We have changed the sentence appropriately as per the reviewer's comment.

288 -Line 263, this the stations. which stations you mean?

289 We have revised the sentence with station details (AF005, AF068, and AF071 in the Laptev Sea
290 and AF100 in the Kara Sea) as per the reviewer's suggestions. Line 313

291 -Line 271, lower C and DIN uptake rates of What? Small or total phytoplankton?

292 We meant small phytoplankton uptake rates here. Revised the manuscript as per the reviewer's
293 suggestions.

294 -Line 279-282, Is this for only small phytoplankton contribution? You need to discuss more on
295 small phytoplankton primary production.

296 N starving can abstain both large and small phytoplankton from achieving potential primary
297 production. However, to an extent small phytoplankton are less severely affected by nutrient
298 limitation than large phytoplankton. Since the small phytoplankton cell size is small nutrient
299 requirement to gain potential primary production is relatively lower compared to the larger
300 phytoplankton cells. However, under very poor nutrient conditions, small phytoplankton may also
301 undergo nutrient starving.

302 We have explained it as follows in the revised manuscript: "In general, experimental and
303 theoretical evidences suggest that smaller cells have higher rates of nutrient uptake per unit
304 biomass and lower half-saturation constants due to their higher surface area to volume ratios

305 (Eppley and Thomas, 1969; Aksnes and Egge, 1991; Hein et al., 1995). And hence, the lower
306 minimum cellular metabolic requirement for small phytoplankton selectively allows them to
307 survive under lower resource concentrations than larger cells (Shuter, 1978; Grover, 1991). And
308 hence, small phytoplankton cells appear to have substantial leads over larger phytoplankton cells
309 under nutrient-limited steady-state environmental conditions (Grover, 1989; Grover, 1991).
310 However, under very poor nutrient conditions, small phytoplankton may also undergo nutrient
311 starving”. Lines : 331-339

312 -Line 308, plankton to facilitate.. phytoplankton or zooplankton?

313 It is phytoplankton. We edited the sentence in the revised manuscript.

314 -Line 327-329, Are the results for turnover time in India for small phytoplankton? Or total
315 phytoplankton? If these results for total phytoplankton, then is it appropriate to compare turnover
316 rates for small phytoplankton in this study?

317 We appreciate the reviewer’s concern. The turnover rates from India is of total phytoplankton
318 community. We admit that it is not wise to compare the turnover times by total phytoplankton with
319 those of small phytoplankton. However, as far as we know there are only few studies reported
320 turnover rates of total phytoplankton. Moreover, there is no report so far regarding the small
321 phytoplankton turnover rate measurements. Lines 381-396

322 -Line 339, ..quantum efficiency/yield.. What “/” means?

323 By “/” we meant “or” here. To avoid the confusion we replaced “efficiency/yield” by only “yield”
324 in the revised manuscript. We also modified the sentence as “The quantum yield for the present
325 study is defined as the uptakes of DIN ($\text{NO}_3^- + \text{NH}_4^+$ uptake rates) and C by unit small
326 phytoplankton Chl *a* fraction which is obtained by dividing uptake rates by Chl *a* concentrations”.

327 –Line 343, it should be like this, ..C and N were observed..

328 Corrected

329 -Line 345-346, N yield.. Is this term correct?

330 We have replaced “N yield” with quantum yield for DIN” and the same done for “C quantum
331 yield”.

332 -Line 350-351, check the sentence!

333 We have revised the sentence as given, “It is a known fact that the impact of global warming on
334 the Arctic Ocean has been introduced rapid changes in its physicochemical properties. Hence, the
335 necessity to trace the changes in primary production pattern in the Arctic Ocean gained attention
336 in the recent era”.

337 -Line 373, Should be “the total primary production (Hodal and Kristiansen, 2008).”

338 Corrected.

339 -Line 376, .large phytoplankton cells (45 μ m). Is this size correct? Check the cell size

340 We apologize for the typo error. It is actually >5 μ m. The correction has been done in the revised
341 manuscript.

396
397 We have added more explanation regarding small phytoplankton uptake metabolism as follows
398 (Lines : 331-339):
399 “In general, experimental and theoretical evidences suggest that smaller cells have higher rates of
400 nutrient uptake per unit biomass and lower half-saturation constants due to their higher surface
401 area to volume ratios (Eppley and Thomas, 1969; Aksnes and Egge, 1991; Hein et al., 1995). And
402 hence, the lower minimum cellular metabolic requirement for small phytoplankton selectively
403 allows them to survive under lower resource concentrations than larger cells (Shuter, 1978; Grover,
404 1991). And hence, small phytoplankton cells appear to have substantial leads over larger
405 phytoplankton cells under nutrient-limited steady-state environmental conditions (Grover, 1989;
406 Grover, 1991). However, under very poor nutrient conditions, small phytoplankton may also
407 undergo nutrient starving”.

439 **Abstract.** Carbon (C) and nitrogen (N) uptake rates by small phytoplankton (0.7-5 μm) in the Kara,
440 Laptev, and East Siberian seas in the Arctic Ocean were quantified using *in situ* isotope labelling
441 experiments for the first time as a part of the NABOS (Nansen and Amundsen Basins
442 Observational System) program during August 21–September 22, 2013. The depth-integrated C,
443 nitrate (NO_3^-), and ammonium (NH_4^+) uptake rates by small phytoplankton showed a wide range
444 from 0.54 to 15.96 $\text{mgC m}^{-2}\text{h}^{-1}$, 0.05 to 1.02 $\text{mgC m}^{-2}\text{h}^{-1}$, and 0.11 to 3.73 $\text{mgN m}^{-2}\text{h}^{-1}$, respectively.
445 The contributions of small phytoplankton towards the total C, NO_3^- , and NH_4^+ were varied from
446 25 to 89%, 31 to 89%, and 28 to 91%, respectively. The turnover times for NO_3^- and NH_4^+ by
447 small phytoplankton during the present study point towards the longer residence times (years) of
448 the nutrients in the deeper waters, particularly for NO_3^- . Relatively, higher C and N uptake rates
449 by small phytoplankton obtained during the present study at locations with less sea ice
450 concentration point toward the possibility of small phytoplankton thrive under sea ice retreat under
451 warming conditions. The high contributions of small phytoplankton toward the total carbon and
452 nitrogen uptake rates suggest capability of small size autotrophs to withstand in the adverse
453 hydrographic conditions introduced by climate change.

454

456 *Key Words:* The Arctic Ocean, nitrogen, carbon, and small phytoplankton.

457

458

459

460 1. Introduction

461 The Arctic Ocean has been always a key attraction for the oceanic expeditions due to its rapid
462 response to changing environmental conditions caused by both natural and anthropogenic factors.
463 It has been reported that the rate of decrease in sea ice extent in the Arctic Ocean is significantly
464 high and eventually caused a decline in sea ice thickness over recent decades (Stroeve et al., 2008;
465 Comiso et al., 2008; Kwok et al., 2009; Overland and Wang, 2013). As an immediate effect, sea
466 ice retreat would benefit the primary production by autotrophs due to increased exposure to
467 sunlight (Hill and Cota, 2005; Gradinger, 2009; Arrigo et al., 2012, Arrigo and van Dijken, 2015;
468 Bélanger et al., 2008; Kahru et al., 2016). It was also reported that primary production in the
469 Barents Sea showed an increase by 30% during the warm period (1989-1995) than the cold one
470 during 1960s (Wassmann et al., 2011; Arrigo et al., 2008). However, as a result of sea ice melting,
471 the ice-algal communities can be replaced by pelagic communities. Although, ice-algal
472 communities are not a large contributor towards the primary production, their absence could
473 potentially alter vertical flux of organic carbon and coupling between the euphotic and benthic
474 zones (Walsh, 1989).

475 Sea surface warming can also result in a strong water column stratification which can reduce
476 nutrient supply to the surface water and consequently a decrease in primary production (Bopp et
477 al., 2001; Lee et al., 2007, 2012; Tremblay and Gagnon, 2009; Li et al., 2009; Martin et al., 2010;
478 McLaughlin et al., 2010; Steinacher et al., 2010; Slagstad et al., 2011; Thomas et al., 2012) and
479 thus alterations in C dynamics in the Arctic Ocean (Arrigo et al., 2008; Bates and Mathis, 2009;
480 Cai et al., 2010). It has been a debatable topic that how phytoplankton communities in the Arctic
481 Ocean would respond to the physical, chemical, and biological stress introduced by global
482 warming. One group of researchers have reported that there has been an enhancement in the annual

483 primary production due to increased light availability and warmer temperature in the Arctic Ocean
484 (Arrigo et al., 2008; Arrigo and Dijken, 2011; Thomas et al., 2012). However, another group
485 suggested that excess moisture fluxes under warmer sea conditions can introduce wider cloud
486 covers during summer and early fall and thus, the possibility of reduction in autotrophic primary
487 production is inevitable (Eastman and Warren, 2010; Vavrus et al., 2012; Bélanger et al., 2013).
488 Water column stratification is also a contrary effect introduced by the global warming which can
489 significantly reduce the vertical mixing of nutrient rich deep waters and that can lower primary
490 productivity (Tremblay and Gagnon, 2009; Lee et al., 2007, 2012; Yun et al., 2015). On other hand,
491 decline in nutrient concentrations in the surface waters while sustained levels in the deeper waters,
492 could be an immediate effect of global warming (Vancoppenolle et al., 2013). Such environment
493 would be adverse for the large phytoplankton communities whose nutrient requirements are higher
494 for achieving potential primary production level (Li et al., 2009). However, small phytoplankton
495 (size range: 0.7-5 μm), which have lower nutrient requirements, are found to be proliferated under
496 such conditions (Li et al., 2009; Daufresne et al., 2009). Hence, understanding the mechanism and
497 processes of small phytoplankton metabolic activities under various environmental conditions
498 would be a crucial aspect of the Arctic Ocean ecosystem research.

499 There have been few studies conducted to understand the fate of small phytoplankton under
500 changing environmental scenario (Li et al., 2009; Yun et al., 2015). They identified that the
501 smallest phytoplankton cells can flourish under such nutrient replete conditions, however; the
502 larger cells decline (Li et al., 2009). And hence, the reduction in community average body size of
503 the autotrophs is expected to be an obvious response to the global warming (Daufresne et al., 2009).
504 Consequently, the primary production assisted by the small phytoplankton would be a substantial
505 part of the Arctic Ocean biogeochemistry. However, the contribution of small phytoplankton

506 towards the autotrophic C and dissolved inorganic nitrogen [here; $\text{DIN} = \text{NO}_3^- + \text{NH}_4^+$] fixation
507 has been one of the least investigated topics in the global ocean research, particularly in the Arctic
508 Ocean (Semiletov et al., 2005; Arrigo and Dijken, 2011; Hill et al., 2017; Yun et al., 2012, 2015;
509 Lee et al., 2007, 2012).

510 Apart from global warming, localized influences are also an important factor in controlling the
511 primary production in the Arctic Ocean. It has been reported that the Arctic Ocean
512 biogeochemistry is mainly governed by the high riverine as well as intrusions of Atlantic and
513 Pacific waters (Shiklomanov et al., 2000; Carmack and Macdonald, 2002; Peterson, et. al., 2002;
514 Anderson et al., 2004). The major rivers flow **into** the Arctic Ocean are the Ob', Lena, Yenisey,
515 and Mackenzie, and numerous smaller ones in both the Amerasian and Eurasian sectors. It is
516 reported that the Ob' and Yenisey Rivers show an increase in their fresh water discharge since
517 1980s (Semiletov et al., 2005; Anderson et al., 2009). These seas situate along the continental shelf
518 of the Arctic Ocean which is known to be the widest and shallowest shelf in the world oceans
519 (Semiletov et al., 2005). These seas are characterized by highly dynamic organic matter production
520 and export to the deeper ocean as well as profound atmospheric exchange of volatile gases
521 (Semiletov et al., 2005; Anderson et al., 2009).

522 There were few studies conducted to estimate the influence of river effluences on C and DIN
523 uptake rates (Lee et al., 2007, 2012; Yun et al., 2015). However, the potential impact of riverine
524 influx on small phytoplankton uptake rates, very relevant for accountability of natural and
525 anthropogenic influences on the Arctic primary production, were not have been subjected to
526 investigation so far. The present study reports **the** first investigation results on small phytoplankton
527 (size: 0.7-5 μm) contribution towards the C, NO_3^- , and NH_4^+ uptake rates in the Kara, Laptev, and
528 East Siberian seas. Considering the global relevance of the Arctic Ocean biogeochemistry, the

529 present study aimed at the (1) estimation of small phytoplankton contribution towards the total
530 primary production as well as NO_3^- and NH_4^+ uptake rates and (2) investigation on various factors
531 influencing the small phytoplankton community efficiency in the Kara, Laptev, and East Siberian
532 Seas.

533 2. Materials and Methods

534 2.1. Study Area

535 The investigations on biochemical parameters and C and DIN transformation rates in the Kara,
536 Laptev, and East Siberian seas were conducted at 19 monitoring stations selected from a total of
537 116 NABOS stations (Fig. 1; Table 1). The geographical boundaries of each sea were defined as
538 per the classification done by Pabi et al. (2008) (Fig. 1). Based on this classification, there were 4,
539 13, and 2 stations were located in the Kara, Laptev, and East Siberian seas. The Kara and East
540 Siberian seas have surface areas almost two times ($926 \times 10^3 \text{ km}^2$ and $987 \times 10^3 \text{ km}^2$, respectively)
541 larger than the Laptev Sea ($498 \times 10^3 \text{ km}^2$) (Jakobsson, 2001). Also, the Laptev and East Siberian
542 seas hold the shallowest zones of the Arctic Ocean basin with a mean depth of 48 m, where the
543 Kara Sea has a mean depth of 131 m (Jakobsson, 2001).

544 2.2. Sampling

545 The sampling was conducted during 21st August to 22nd September, 2013 onboard the Russian
546 vessel “*Akademik Fedorov*”. The temperature and salinity were measured using a Seabird
547 SBE9plus CTD (conductivity-temperature-depth tool) equipped with dual temperature (SBE3) and
548 conductivity (SBE4) sensors. Samples for major inorganic nutrients [NO_3^- , nitrite (NO_2^-), NH_4^+ ,
549 phosphate (P), and silicate (Si)] were collected using Niskin bottles attached to the CTD device
550 and analysis was performed onboard using an Alpkem Model 300 Rapid Flow Nutrient Analyzer

551 (5 channels) based on Whitley et al. (1981). The chlorophyll *a* (Chl *a*) samples for the small
552 phytoplankton fraction were obtained from 3 light depths (100, 30, and 1%). The preparation of
553 Chl *a* samples was based on the standard procedure reported in the previous studies (Lee and
554 Whitley, 2005; Lee et al., 2012). Water samples for small Chl *a* fractions were sequentially
555 filtered through 5µm Nucleopore and then 0.7µm pore-sized Whatman GF/F filters (47 mm).
556 Further, the GF/F filters were wrapped in aluminum foil and kept frozen at -80 °C until the analysis.
557 During the analysis, the Chl *a* fractions from the filters were extracted using 90% acetone treatment
558 at -5°C for 24 hours. The extracted Chl *a* samples were undergone spectrophotometric analysis on
559 board using a pre-calibrated Turner Designs model 10-AU fluorometer. Samples for the C and
560 DIN uptake rates were collected from six *in situ* depths of light levels (100, 50, 30, 12, 5, and 1%)
561 determined at each station by the use of euphotic depth on the basis of Lambert-Beer's law.
562 Underwater PAR sensor (and/or optical instruments) could not be used due to logistic problems
563 and the euphotic depth was calculated using the Secchi depth which is a widely used method (Son
564 et al., 2005; Tremblay et al., 2000; Lee et al. 2012; Bhavya et al., 2016; 2017; Lee et al., 2017a,
565 2017b).

566 **2.3 ¹³C and ¹⁵N labeling experiments**

567 The estimation of C and DIN uptake rates were done using ¹³C and ¹⁵N dual isotope labeling
568 experiments (Dugdale and Goering, 1967; Slawyk et al 1977; Dugdale and Wilkerson, 1986).
569 Seawater samples at each light depth were collected using Niskin bottles attached to the CTD
570 Rosette and transferred to acid-cleaned polycarbonate incubation bottles (approximately 1 L)
571 wrapped with neutral density light filters (LEE filters) to match with desired light levels.
572 Immediately, samples were spiked with 98-99 % enriched tracer solutions of NaH¹³CO₃, K¹⁵NO₃,
573 or ¹⁵NH₄Cl at concentrations of ~0.3 mM, ~0.8µM, and ~0.1µM for the estimations of C, NO₃⁻,

574 and NH_4^+ uptake rates, respectively. Further, the samples were subjected to 4-6 hrs of incubation
575 in big transparent Plexiglas incubators on deck under natural light conditions with provided
576 running surface seawater. Immediately after the incubation, 0.3 L of incubated samples were
577 filtered through pre-combusted GF/F filters (25mm diameter) for the total uptake rate estimation.
578 The samples for small fraction, sub-samples (0.5 L) of the incubated waters were passed through
579 5 μm Nuclepore filters (47 mm) to remove large phytoplankton cells ($>5 \mu\text{m}$) and then the filtrate
580 was passed through pre-combusted GF/F (25 mm) for the small phytoplankton (Lee et al., 2013).
581 The values for large phytoplankton in this study were obtained from the difference between small
582 and total fractions (Lee et al., 2013). Samples were kept frozen ($-20 \text{ }^\circ\text{C}$) until the mass
583 spectrometric analysis (Finnigan Delta+XL) at the stable isotope laboratory of University of
584 Alaska Fairbanks, US. The uncertainties for $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ measurements were $\pm 0.1\text{‰}$ and $\pm 0.3\text{‰}$,
585 respectively. **DIN uptake rates of small phytoplankton were estimated using the mathematical**
586 **formula given by Dugdale and Goering (1967).**

$$587 \text{ DIN uptake rate} = P * \Delta I_p / (T * (I_0 S_a + I_r S_t) / (S_a + S_t) - I_0)$$

588 Where: P is the amount of particulate N in the post incubation sample, ΔI_p is the increase in ^{15}N
589 atom% in particulate N during incubation, S_a and S_t are ambient and added NO_3^- (or NH_4^+)
590 concentrations, respectively, I_r and I_0 are ^{15}N atom% of added tracer and natural ^{15}N atom%, and
591 T is the incubation time period. This equation assumes no formation of nutrient during incubation
592 and therefore rates presented here are potential rates. **Similarly, C uptake rates also were calculated**
593 **using the same equation where; P denotes the particulate organic C and S_a and S_t are ambient**
594 **dissolved inorganic carbon and added ^{13}C tracer concentrations, respectively. I_r and I_0 are ^{13}C atom%**
595 **of added tracer and natural ^{13}C atom%, respectively (Slawyk et al., 1977).**

596 3. Results and discussions

597 3.1 Environmental parameters in the Arctic Ocean

598 The biological, chemical, and physical properties of the Arctic Ocean are mainly controlled by the
599 circulation patterns governed by the Pacific and Atlantic Ocean waters (Anderson et al., 2004;
600 Quadfasel, 2005) along with the river inputs (Peterson et al., 2002). The nutrient rich low saline
601 (<33 PSU) Pacific Ocean waters and nutrient replete relatively more saline (≈ 34.8 PSU) Atlantic
602 Ocean waters collectively regulate the biogeochemical activities of the Arctic Ocean (Maslowski
603 et al., 2004). The present study was conducted during late summer season where the sea surface
604 temperature (SST) was ranged from -1.76 °C to 1.62 °C. The sea surface salinity (SSS) during the
605 study period varied from 28.29 to 33.44 PSU (Table 1) which could be due to the influence of both
606 circulation pattern as well as fresh water inputs. The present study retrieved sea ice concentration
607 (SIC) from National Snow & Ice Data Center obtained from 2013 cruise. The results show that the
608 SIC has ranged from 0 % to 100 % (Table 1).

609 3.2 Carbon and nitrogen uptake rates by small phytoplankton

610 Fig. 2 shows the depth profiles C, NO_3^- , and NH_4^+ uptake rates per hour in the Laptev, Kara, and
611 East Siberian seas. Only a few stations showed significant subsurface maxima for the C, NO_3^- , and
612 NH_4^+ uptake rates during the present study where the rest of them exhibited no significant variation
613 throughout euphotic zone. AF019 station showed an exceptionally higher C, NO_3^- , and NH_4^+
614 uptake rates, in general, with a sharp subsurface maxima. The depth-integrated C, NO_3^- , and NH_4^+
615 uptake rates by small phytoplankton in the East Siberian Sea were observed to be very low
616 compared to those of other seas (Table 2, Figs. 3 & 4). The depth-integrated C uptake rates by
617 small phytoplankton showed a wide range from 0.54 to $15.96 \text{ mg C m}^{-2}\text{h}^{-1}$. The depth-integrated

618 NO_3^- uptake rates ranged from 0.05 to 1.02 mg N $\text{m}^{-2}\text{h}^{-1}$, where NH_4^+ uptake rates varied from
619 0.11 to 3.73 mg N $\text{m}^{-2}\text{h}^{-1}$. The station AF019 showed the maximum small phytoplankton uptake
620 rates for C (15.96 mg C $\text{m}^{-2}\text{h}^{-1}$), NO_3^- (1.02 mg N $\text{m}^{-2}\text{h}^{-1}$), and NH_4^+ (3.73 mg N $\text{m}^{-2}\text{h}^{-1}$). The
621 contribution of small phytoplankton towards the total uptake is also very high at station AF019
622 (Table 2). The exceptionally high uptake rates for C, NO_3^- , and NH_4^+ obtained at station AF019 is
623 indeed very interesting. Similarly very high particulate organic carbon as well as nitrogen
624 concentration and specific small phytoplankton uptake rates compared to other stations were also
625 observed at station AF019. However, chlorophyll concentrations for the small phytoplankton
626 community did not show such higher values when compared to other stations. Based on the
627 background data obtained during the present study could not give a possible reason to the high
628 uptake rates. We assume that the higher metabolic rates can be due to presence of different
629 autotrophic communities which are different from other sampling locations. Unfortunately, we
630 could not obtain species identification data during the present study. The lowest C, NO_3^- , and NH_4^+
631 uptake rates were observed at AF044 and AF041. The highest SIC (100% and 60% at AF044 and
632 AF041, respectively) in this region might be a reason for lower primary productivity due to light
633 limitation.

634 **3.3 Sea ice and small phytoplankton primary production**

635 The previous investigations on SIC over the Arctic Ocean proved that, during winter, the high ice
636 formation leads to expelling of salt content to the surrounding water. This introduces a relatively
637 high saline as well as density water layer at the surface or just below the sea ice layer than
638 surrounding. Such condition leads to sinking of very cold and saline surface waters and
639 replacement by nutrient rich deeper water which is less dense and a little warmer. This process
640 leads to deep vertical mixing and replenishment of surface nutrient inventories (Niebauer et al.,

1990; Falk-Petersen et al., 2000). However, during spring, melting of sea ice results in a strong surface ocean stratification where the nutrient-rich waters are being exposed to a light availability to create favorable conditions for the phytoplankton growth (Kirk, 1983; Niebauer et al., 1990; Falk-Petersen et al., 2000). It is also reported that the increasing atmospheric temperature due to global warming has been considerably caused a reduction in SIC in the Arctic Ocean over the past three decades, with a rapid decrease in recent years (Levi, 2000; Parkinson, 1999).

Since the ice cover has significant role in controlling primary production, the dynamics of SIC is an integral part of the Arctic Ocean research (Arrigo et al., 2008; Ardyna et al., 2014; Kahru et al., 2016). It has been reported that that the reduction in SIC would facilitate the photosynthetic activity and increase CO₂ intake by the seas (Anderson and Kaitin, 2001; Bates et al., 2006; Kahru et al., 2016). Apparently, it can cause a relative decline in the contribution by algae growing within the sea ice (Subba Rao and Platt, 1984; Legendre et al., 1992; Gosselin et al., 1997), although sea ice community contributes only less than 10% of the Arctic Ocean C sequestration (Clasby et al., 1973; Horner and Schrader, 1982). A detailed study conducted on inter-annual variations in SIC and primary production by Kahru et al. (2016) suggested that the primary production gets enhanced with decline in SIC. Kahru et al. (2016) reported that decrease in SIC initially starts from June onwards in the northeastern Barents Sea and between Greenland and the North American continent with an increase in primary productivity. This extends to the Kara and Laptev seas during July-August and these areas exhibit a gradual enhancement in primary productivity. Further, this process migrates towards the off Siberia and eventually in the Beaufort and Chukchi seas. However, the major enhancement of primary production generally occurs in the Laptev and Barents seas (Kahru et al., 2016). In agreement to this, our results also show a relatively lower SIC and higher small phytoplankton C and DIN uptake rates in the Laptev Sea region (Table 2, Figs. 3 & 4). The

664 maximum SIC in the Laptev Sea was observed at station AF071 which is 65%. The Kara Sea was
665 mostly void of ice cover and only one station (AF095) was observed with a SIC of 40%. Relatively
666 lower small phytoplankton C and DIN uptake rates were observed at both the stations in the East
667 Siberian Sea (AF041: 60% and AF044: 100%) where the SIC was observed to be the maximum
668 among all the stations. However, there was no significant inverse correlation of small
669 phytoplankton C and DIN uptake rates with SIC found during the present study (Figure not shown).
670 This could be due to influence of other environmental constraints such as low nutrients and
671 temperature on metabolic activities of small phytoplankton.

672 The investigations conducted in the Amundsen Sea, Antarctic Ocean reported that there is no
673 significant difference in small phytoplankton C uptake rates between polynya and non-polynya
674 regions. The depth integrated small phytoplankton C uptake rates obtained from polynya and non-
675 polynya regions in the Amundsen Sea were ranged from 58.6–193 mg C m⁻²d⁻¹ (126 ± 55.2 mg C
676 m⁻²d⁻¹) and 62.2–266 mg C m⁻²d⁻¹ (124 ± 69.3 mg C m⁻²d⁻¹), respectively (Lee et al., 2017a).
677 These values show that depth integrated small phytoplankton C uptake rates reported from the
678 Amundsen Sea from both polynya and non-polynya regions are relatively higher than those
679 obtained from the Arctic Ocean during the present study (5.86-191mg C m⁻²d⁻¹; Average=37.7±
680 41.6). The daily NO₃⁻ uptake rates of small phytoplankton obtained from the Amundsen Sea were
681 7.5–26.6 mg N m⁻²d⁻¹ (16.7 ± 7.8 mg N m⁻²d⁻¹) and 6.1–40.9 mg N m⁻²d⁻¹ (20.1 ± 13.1 mg N
682 m⁻²d⁻¹) and those of NH₄⁺ uptake rates varied from 9.1–22.4 mg N m⁻²d⁻¹ (15.8 ± 6.4 mg N m⁻²d⁻¹)
683 and 9.9–81.1 mg N m⁻²d⁻¹ (30.7 ± 24.5 mg N m⁻²d⁻¹), respectively, for the non-polynya and
684 polynya regions. Similar to C uptake rates, small phytoplankton uptake rates for NO₃⁻ (0.75-12.2
685 mg N m⁻²d⁻¹; 3.21±2.61 mg N m⁻²d⁻¹) and NH₄⁺ (2.68-69.3 mg N m⁻²d⁻¹; average: 16.12±14.54
686 mg N m⁻²d⁻¹) were also significantly lower than that of Amundsen Sea. The lower small

687 phytoplankton uptake rates in the Arctic waters compared to Antarctic waters can be possibility
688 due to the lower nutrient concentrations and co-limitation of N in the Arctic waters (Harrison and
689 Cota, 1991). Sakshaug & Holm-Hansen (1984) has reported that the maximum Arctic nutrient
690 concentrations are typically lower than minimum Antarctic concentrations.

691 **3.4 Nutrient sources and influence on small phytoplankton primary production**

692 The shallow water column depths and the existence of long coastline along with river runoff
693 provide a wide opportunity for the autotrophs in the Arctic Ocean to get sufficient light and
694 nutrients (Kirk, 1983). Also, the Arctic Ocean is known to be a large receptor of freshwater
695 discharge which exceeds 4000 km³ per annum (Shiklomanov, 2000; Carmack and Macdonald,
696 2002). The riverine discharges may have a great role in keeping those stations nearby river inlet
697 distinctive in physico-chemical conditions. Similarly, the freshwater discharge from the six largest
698 Eurasian rivers increased by 7% during 1936 - 1999 (Peterson et al., 2002). Among the various
699 seas in the Arctic Ocean, the Kara and Laptev seas are known to be the first and second largest
700 receptors, respectively, of total organic carbon fluxes while the East Siberian Sea receives the least
701 (Rachold et al., 2000).

702 Nitrite+nitrate concentrations in most stations were observed to be homogeneous in the water
703 column up to a depth of 20 m (approximately 30% light depth); however, increased exponentially
704 towards the bottom waters (Figure not shown). The depth profiles of NH₄⁺ and P did not show any
705 significant variation throughout the euphotic zone (Figure used in Lee et al., unpublished).
706 However, the nutrient concentrations were considerably distinct among the stations. The depth-
707 integrated NO₂⁻+NO₃⁻ concentrations varied between 22.3 and 189 mmol m⁻². The depth-
708 integrated concentrations of P and Si were ranged from 7.62 to 35.4 mmol m⁻² and 19.5 to 308

709 mmol m⁻², respectively (Table 1). Generally, high concentrations of NO₂⁻+NO₃⁻ and phosphate
710 were found at AF005, AF068, and AF071 in the Laptev Sea and one station in the Kara Sea (AF100)
711 and they were relatively much higher than those of the East Siberian Sea (Table 1, Figs. 3 & 4).
712 However, the Si concentrations were higher in the East Siberian Sea in comparison with the other
713 two seas. These results are comparable with the earlier studies conducted by Codispoti and
714 Richards (1968). They suggested that the concentrations of P and NO₃⁻ were so low as to indicate
715 nutrient limitation for phytoplankton production in the upper layers.

716 The details of euphotic depths and depth-integrated nutrient concentrations are shown in Table 1.
717 The euphotic depths observed are different in almost all of the stations ranging from 33 to 76 m.
718 However, the data from our present study did not show any dependency of depth- integrated
719 nutrient budget with euphotic depth. For example, AF019, AF080, and AF095 stations have deeper
720 euphotic zone, however; they are not having depth integrated NO₂⁻+NO₃⁻ concentrations close to
721 the highest values obtained at AF068, AF071, and AF005 which are having relatively shallower
722 euphotic depths. The depth-integrated P values also showed higher values at stations (AF019,
723 AF068, AF100, AF080, AF095, and AF091) with both deeper and shallower euphotic depths.
724 Hence, the variation in euphotic depths seems to be insignificant in determining the nutrient
725 budgets in the present study area.

726 In reference to the stations (AF005, AF068, and AF071 in the Laptev Sea and AF100 in the Kara
727 Sea) nearby the river inlets were observed with relatively higher nutrient concentrations (Table 1).
728 The sampling locations away from the river inputs are mostly invaded by the nutrient poor Atlantic
729 waters instead of nutrient rich Pacific water. In another way, the Pacific Ocean nutrient inputs are
730 generally restricted to the Chukchi Sea and the Amerasian Basin (Carmack et al., 1997; Dmitrenko
731 et al., 2006). It is worth noticing that all the sampling locations in the Arctic Ocean showed

732 significantly lower small phytoplankton C and DIN uptake rates possibly due to lack of light and
733 nutrients. The nutrient stoichiometry analyses suggested that the Arctic Ocean waters are N
734 starving and the N:P (here N = DIN: $\text{NO}_2^- + \text{NO}_3^- + \text{NH}_4^+$ and P: PO_4^{3-}) ratios are always below the
735 Redfield's ratio which is 16:1 (mol: mol) (Redfield, 1963; Sakshaug, 2004). The relative
736 abundances of micronutrients are also important factors to control the primary production (Glibert
737 et al., 2013; Bhavya et al., 2016, 2017). The DIN:P observed during the current study ranged from
738 2.60 to 16.4 with an average of 6.6 ± 3.0 which is also in agreement with the previous studies
739 reported. These ratios point towards the N-starvation of phytoplankton which can potentially
740 abstain them from growing to a bloom. It is reported that such cases with less nutrient
741 concentrations are generally less starving for small phytoplankton size range from 0.7-5 μm and
742 they appeared to be a dominant in the euphotic water columns (Lee and Whitedge, 2005; Li et al.,
743 2009; Yun et al., 2015).

744 In general, experimental and theoretical evidences suggest that smaller cells have higher rates of
745 nutrient uptake per unit biomass and lower half-saturation constants due to their higher surface
746 area to volume ratios (Eppley and Thomas, 1969; Aksnes and Egge, 1991; Hein et al., 1995). And
747 hence, the lower minimum cellular metabolic requirement for small phytoplankton selectively
748 allows them to survive under lower resource concentrations than larger cells (Shuter, 1978; Grover,
749 1991). And hence, small phytoplankton cells appear to have substantial leads over larger
750 phytoplankton cells under nutrient-limited steady-state environmental conditions (Grover, 1989;
751 Grover, 1991). However, under very poor nutrient conditions, small phytoplankton may also
752 undergo nutrient starving.

753

754 **3.5 Nutrient co-limitation**

755 Nutrient co-limitation is a major problem facing by marine phytoplankton in the oligotrophic as
756 well as pelagic ecosystems. The recent studies suggested that the maximum uptake of
757 phytoplankton generally occurs when nutrient stoichiometry is close to the Redfield's ratio which
758 is 16:1 (Li et al., 2011; Glibert et al., 2013; Bhavya et al., 2016, 2017), irrespective of individual
759 nutrient concentration. Since the present study dealt with a completely different ecosystems with
760 high SIC, low nutrients and SSTs, understanding the influence of DIN:P would be challenging. In
761 agreement to this, there was no significant correlations observed between C, NO_3^- , and NH_4^+
762 uptake rates with DIN:P during the present study. However, Fig. 5 shows a weak, although a
763 positive correlation of small phytoplankton contribution towards with DIN:P. It indicates the
764 possibility of small phytoplankton efficiency to peak at nutrient stoichiometry close to Redfield's
765 ratio. However, the lack of sufficient stations with higher DIN:P values limits the present study
766 from claiming the influence of nutrient stoichiometry on small phytoplankton contribution. It is
767 also important to note that the stations are located at geographical locations with diverse
768 hydrographical parameters. However, on the basis of few researches conducted from various parts
769 of oceanic and estuarine regions, it is proven that DIN:P holds a strong control on total C and DIN
770 uptake rates (Li et al., 2011; Glibert et al., 2013; Bhavya et al., 2016, 2017). Although there was
771 no significant correlation obtained between small phytoplankton uptakes and DIN:P, the N co-
772 limitation in the Arctic Ocean is clearly seen (Table 1). That means, the relative abundances of
773 DIN and P are highly important for proper functioning of C and DIN uptake mechanism by
774 autotrophs.

775

776 3.6 Turnover times of nutrients

777 The present study shows that DIN co-limitation persists in the Arctic Ocean can be one of the
778 major problems which can potentially limits the small phytoplankton contribution. In that case,
779 any inorganic N substrate introduced to the surface waters might be immediately used by the
780 phytoplankton to facilitate the organic matter production under the favorable environmental
781 conditions. The turnover time for any substrate is an important measurement to estimate how rapid
782 an N substrate can be consumed. The estimation of turnover time is done by dividing substrate
783 concentrations with corresponding uptake rates. Figs. 6 & 7 shows the turnover times for NO_3^- and
784 NH_4^+ substrates when small phytoplankton communities are the only consumers exist. Fig. 7
785 shows that turnover times for NH_4^+ substrate (within 500 hours) in the surface waters is longer,
786 however; relatively faster than NO_3^- in upper layers of euphotic zone in almost all the stations in
787 the Arctic Ocean. However, the bottom waters of euphotic zone showed relatively longer (1000-
788 1700 hours) turnover times for NH_4^+ substrate compared to the surface waters. The sampling
789 location in East Siberian Sea (AF044) was observed with relatively longer turnover times for both
790 NO_3^- and NH_4^+ substrates at the surface layers (Figs. 6 & 7) possibly due to the lower uptakes rates
791 over there. Continuous supply of nutrients through rivers and less efficient DIN uptake rates might
792 be major reasons for longer turnover times. Compared to NH_4^+ , NO_3^- is consumed in distinctively
793 longer periods as 14 folds at the surface waters and 25 folds in the bottom of euphotic zone.
794 Primarily, such difference is due to the relative preference for NH_4^+ by the small phytoplankton
795 and secondly due to the high concentrations of NO_3^- in the deep waters than NH_4^+ concentrations.
796 The research outputs from a tropical eutrophic estuary in India has showed rapid turnover time
797 (3.4 - 232 hrs for NH_4^+ and 7.13-2419 hrs for NO_3^-) by total phytoplankton communities for DIN
798 substrates despite of higher nutrient concentrations (Bhavya et al., 2016). In general, inhibition for

799 NO_3^- uptake is a very common phenomenon when higher NH_4^+ concentrations occurs (e.g., Glibert,
800 1982; Harrison et al., 1987; McCarthy et al., 1999; Bhavya et al. 2016). It is also very likely to
801 have different turnover times with the similar DIN concentrations under different hydrographic
802 properties those can govern the C and DIN metabolism over there.

803 3.7 Quantum yield

804 During the present study, size-fractionated Chl *a* concentrations at three light levels (100, 30, and
805 1 %) were measured. The comparative analysis with the total Chl *a* fraction suggests that small
806 phytoplankton communities are major contributors in the Laptev, Kara, and East Siberian seas
807 (Figure not shown; data used from Lee et al. unpublished). The results showed significantly high
808 contributions of small phytoplankton towards the total Chl *a* at all the three light levels (63.3 (S.D.
809 = $\pm 17.5\%$), 61.4 (S.D. = $\pm 19.9\%$), and 59.0% (S.D. = $\pm 18.4\%$) at 100, 30, and 1%, respectively).

810 The efficiency of Chl *a* in small phytoplankton communities to fix C and DIN is a matter of
811 concern in the Arctic Ocean. The quantum yield for the present study is defined as the efficiency
812 of unit Chl *a* in the small phytoplankton communities to fix DIN and C, which is calculated by
813 dividing uptake rates by Chl *a* concentration. The lower temperatures and salinities, ice cover, and
814 the poor light availability can potentially lower quantum yields. The quantum yield for C and DIN
815 are shown in Figs. 8 and 9, respectively. The maximum yields for both C and DIN were observed
816 at AF091 for 100 and 30 % light depths. However, the quantum yield for C at 1% light levels in
817 all the stations were observed to be very low more likely due to light limitation (Talling, 1957).
818 Although the quantum yield for DIN was lower at 1% in comparison with other two light levels
819 the drastic drop in quantum yield for DIN at the 1% light levels, like quantum yield for C, was not

820 observed. This can be due to the existence of significant NH_4^+ uptake rates in the light scarce
821 conditions.

822 **3.8 Small and large phytoplankton contributions**

823 It is a known fact that the impact of global warming on the Arctic Ocean has been introduced rapid
824 changes in its physicochemical properties. Hence, the necessity to trace the changes in primary
825 production pattern in the Arctic Ocean gained attention in the recent era. It has been reported that
826 the contribution of small phytoplankton towards the total C and DIN fixations would be increasing
827 under the warming conditions (Li et al., 2009, Thomas et al., 2012). A significant number of total
828 primary production estimates is available from the Arctic Ocean (Platt et al., 1982; Wassmann et
829 al., 2011; Vedernikov et al., 1994; Gosselin et al., 1997; Boetius and Damm, 1998; Tremblay et
830 al., 2002; Arrigo et al., 2008; Lee et al., 2007; 2012, 2017a; Arrigo and Dijken, 2011; Yun et al.,
831 2012, 2015; Kahru et al., 2016; Lee et al., unpublished). However, a deep understanding regarding
832 the boosting up of small phytoplankton under warming conditions and their contributions towards
833 the total primary production is still rudimentary.

834 The studies from the various oceanic bodies suggest that the small phytoplankton contribution to
835 the total annual C and DIN fixation varies between 20 to 65% (Agawin et al., 2000; Hodal and
836 Kristiansen, 2008; Joo et al. 2017; Lee et al. 2017a). The contributions of small phytoplankton to
837 total C uptake rates were significantly higher in the Amundsen Sea with an average of 50.8 %
838 ($\pm 42.8\%$) and 14.9 % ($\pm 8.4\%$), respectively, for the non-polynya and polynya regions (Lee et al.
839 2017a). The contributions of small phytoplankton to the total NO_3^- uptake rates were 28.2 %
840 ($\pm 15.9\%$) in the non-polynya region and 18.1 % ($\pm 6.8\%$) in the polynya region, respectively.
841 Similar to C assimilation rates, small phytoplankton contributions towards total NH_4^+ uptake rates
842 were higher in both non-polynya (52.8%: $\pm 40.5\%$) and polynya (31.6%; $\pm 10.1\%$) regions (Lee et

843 al., 2017a). Similarly, small phytoplankton contribution in the western Canada basin in the Arctic
844 Ocean was reported to be 64% (Yun et al., 2015). A recent study from the Chukchi Sea reported
845 that the average contributions of small phytoplankton to C and total DIN uptake rates were
846 approximately 32% (S.D. = $\pm 24\%$) and 37% (S. D. = $\pm 26\%$), respectively (Lee et al., 2013).
847 Similar investigations conducted in the northern Barents Sea found that small phytoplankton
848 contributed almost half (46%) of the total primary production (Hodal and Kristiansen, 2008). The
849 MODIS-derived data in the Ulleung Basin from 2003 to 2012 suggested that the annual
850 contribution by small phytoplankton communities, in general, ranges from 19.6% to 28.4% with
851 an average of 23.6% (S.D. = $\pm 8.1\%$) (Joo et al., 2017). This study suggested that the large
852 phytoplankton communities are the major contributors towards the primary production in the
853 Ulleung Basin. Similarly, Legendre et al. (1992) reported that primary production in the high-
854 latitude Arctic region waters, in general, was dominated by large phytoplankton cells ($>5\mu\text{m}$),
855 whereas the standing stock was dominated by small cell-sized phytoplankton ($0.7\text{--}5\mu\text{m}$) due to
856 strong grazing stress on large cells.

857 The present study provides the first ever report on small phytoplankton contribution towards the
858 total primary production in the Kara, Laptev, and East Siberian seas in the Arctic Ocean. The
859 results from the study suggests that the small phytoplankton potentially contributed 24 to 89%, 32
860 to 89%, and 28 to 91 %, towards the total C, NO_3^- , and NH_4^+ uptake rates in the whole study region.
861 Large phytoplankton contributions (total-small phytoplankton contributions) towards the total
862 uptake rates obtained during the present study is given in Table 2. The assessments by Tremblay
863 et al. (2000) suggests that large phytoplankton can fix relatively more C per unit NO_3^- and thus
864 export more C than small phytoplankton. However, the results from the present study show that
865 the large phytoplankton communities in the Arctic Ocean could contribute only an average of 40%,

866 34%, and 35% towards the total C, NO_3^- , and NH_4^+ uptake rates, respectively. And hence, small
867 phytoplankton appears to be the major contributor of C, NO_3^- , and NH_4^+ uptake with percentage
868 contributions of 60%, 66% and 65%, respectively, in the Laptev, Kara, and East Siberian seas.
869 These values are much higher than the global average contribution (39%) of small phytoplankton
870 production assessed by Agawin et al. (2000).

871 **4. Conclusions**

872 The present study attempted to estimate small phytoplankton contributions towards the total C,
873 NO_3^- , and NH_4^+ uptake rates in the Kara, Laptev, and East Siberian seas. The contributions of
874 small phytoplankton towards the total C, NO_3^- , and NH_4^+ uptake rates ranged 25 - 89%, 31 - 89%,
875 and 28 - 91%, respectively, in the Arctic Ocean. There was no significant influence of ice cover
876 on uptake rates was observed; however, the stations with high SIC were, in general, showed low
877 surface small phytoplankton uptake of C, NO_3^- , and NH_4^+ . It is also observed that the DIN:P can
878 potentially play a major role in controlling the small phytoplankton contributions towards the DIN
879 uptake rates by small phytoplankton. The significant contributions of small phytoplankton indicate
880 their efficiency to withstand the hostile conditions such as low nutrients, changing SST, and high
881 ice cover. However, to understand influence of global warming on small phytoplankton activity,
882 growth, and community shift, long term *in situ* analyses as well as laboratory manipulations
883 experiments are highly recommended.

Table 2. The contribution of small and large phytoplankton towards water column C, NO₃⁻, and NH₄⁺ uptake rates. The units for column integrated C, and DIN uptake rates are mg C m⁻²h⁻¹ and mg N m⁻²h⁻¹, respectively. The starred values indicate possibly wrong data due error in uptake rate measurement.

Sector	Stn. Name	Small C uptake rates	Total C uptake rates	Small phytoplankton C uptake contribution (%)	Small NO ₃ ⁻ uptake rates	Total NO ₃ ⁻ uptake rates	Small phytoplankton NO ₃ ⁻ uptake contribution (%)	Small NH ₄ ⁺ uptake rates	Total NH ₄ ⁺ uptake rates	Small phytoplankton NH ₄ ⁺ uptake contribution (%)	Large phytoplankton C uptake contribution (%)	Large phytoplankton NO ₃ ⁻ uptake contribution (%)	Large phytoplankton NH ₄ ⁺ uptake contribution (%)

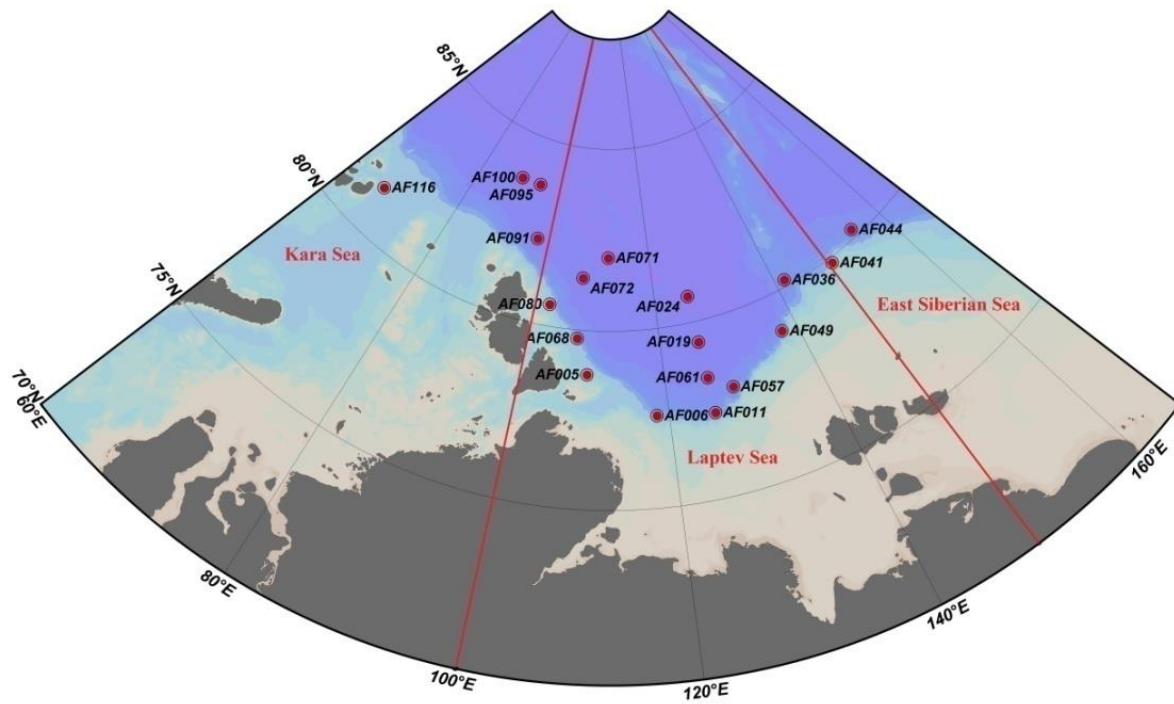

Figure 1. Sampling locations in the Kara, Laptev, and East Siberian Seas in the Arctic Ocean. The red straight lines indicate the geographic boundaries to define the seas as per Pabi et al. (2008).

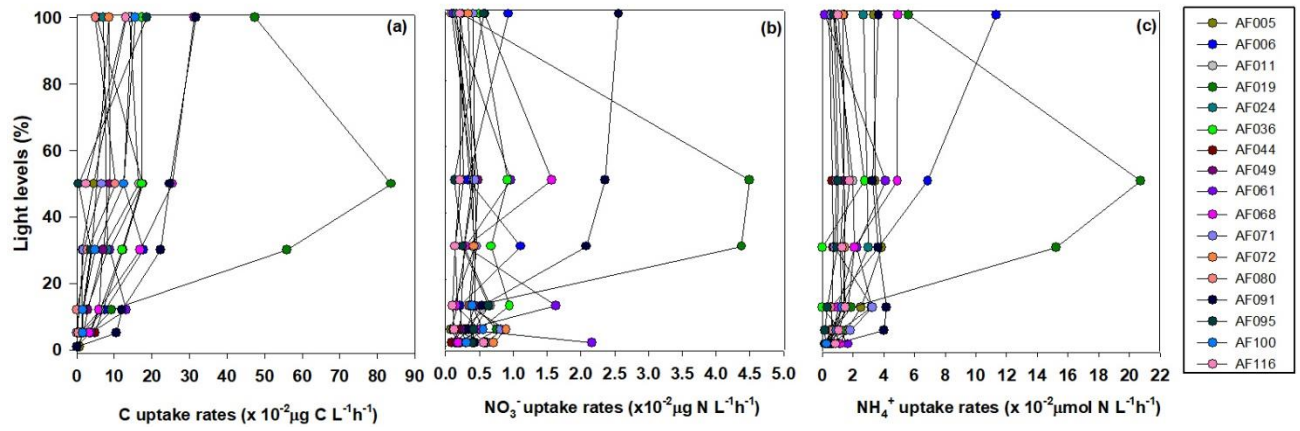

Figure 2. Depth wise small phytoplankton uptake rates of C, NO_3^- , and NH_4^+ in the Kara, Laptev, and East Siberian Sea.

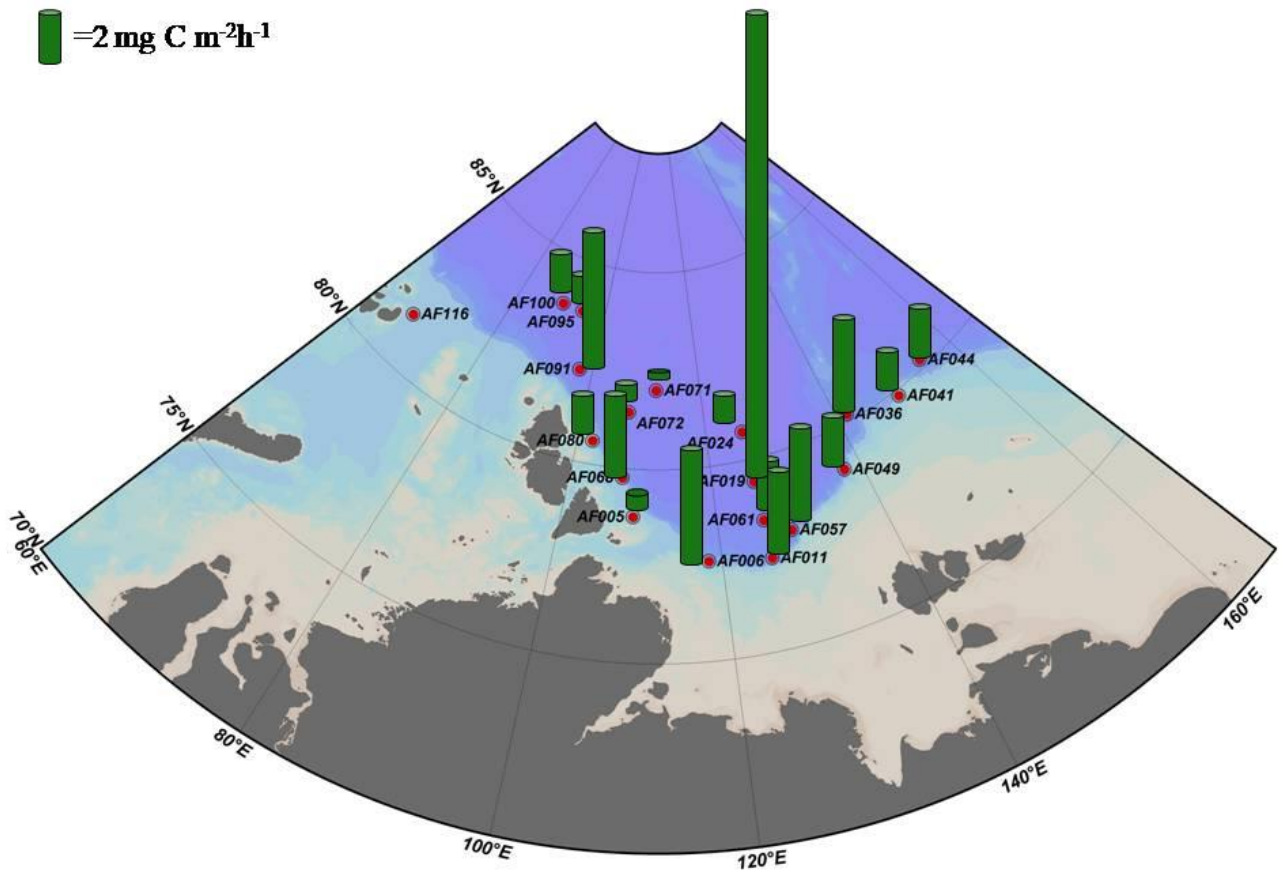

Figure 3. The depth-integrated small phytoplankton C uptake rates in the sampling locations.

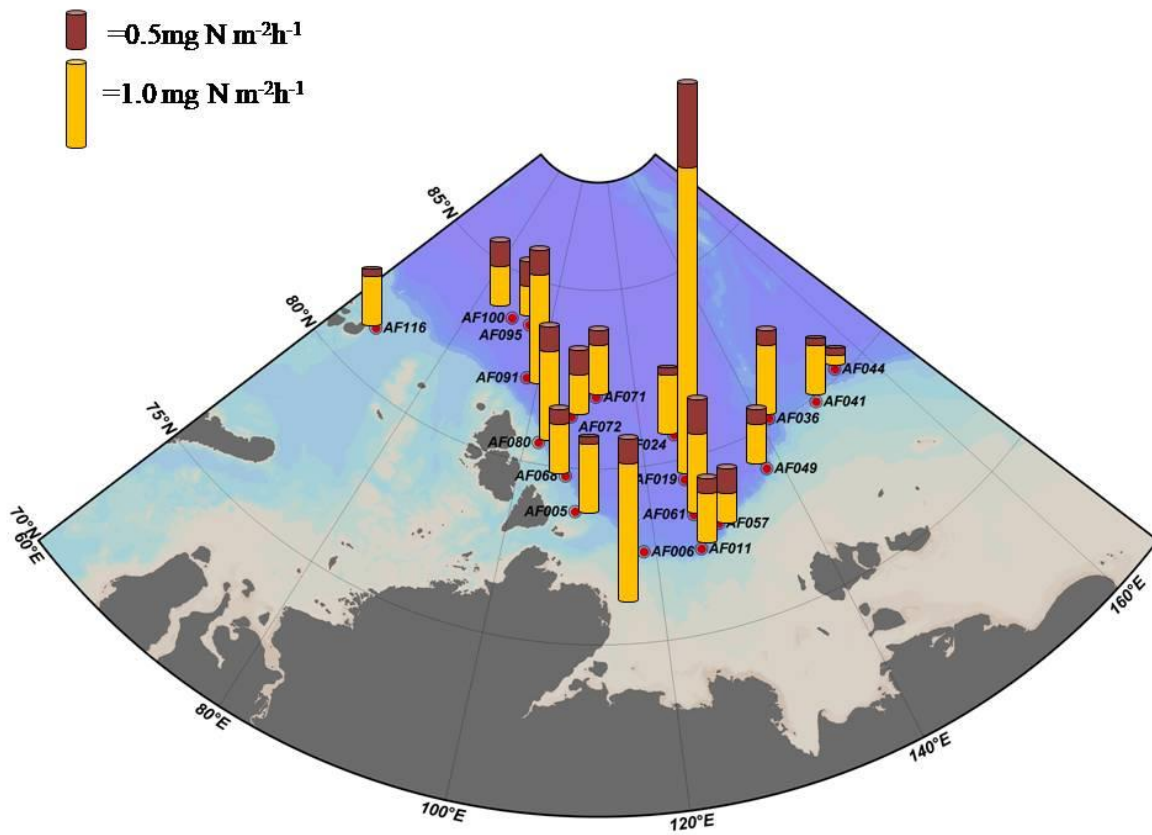

Figure 4. The depth-integrated small phytoplankton NO_3^- , and NH_4^+ uptake rates in the sampling locations. The maroon and yellow cylinders indicate the small phytoplankton NO_3^- and NH_4^+ depth-integrated uptake rates, respectively.

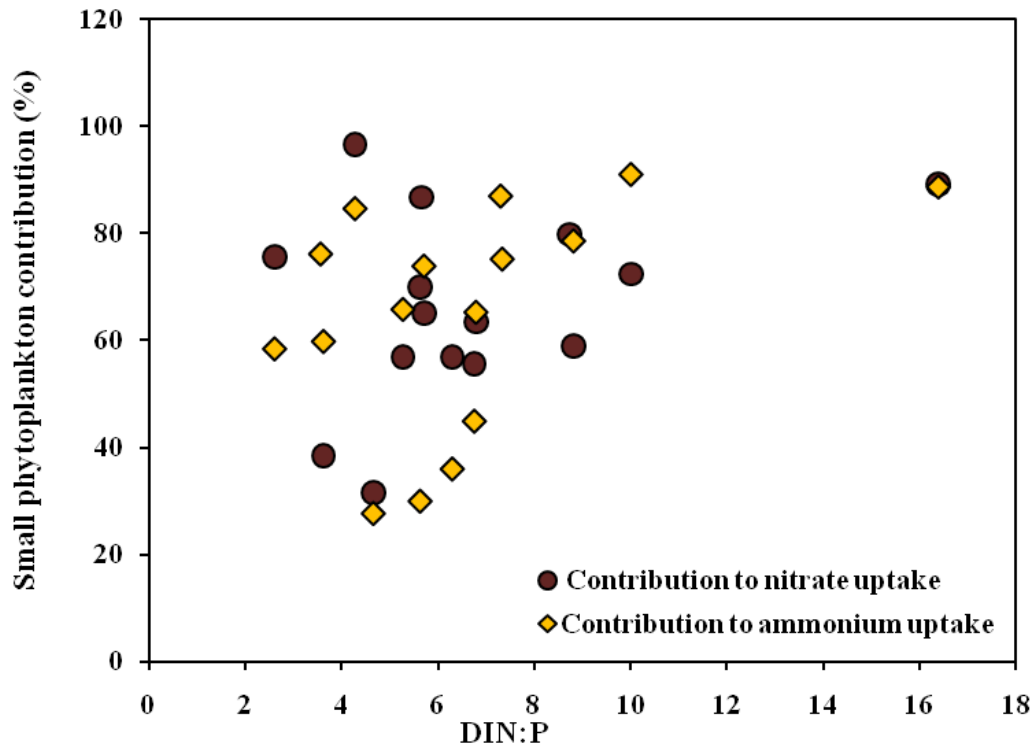

Figure 5. The relationship of contribution of small phytoplankton towards the total NO_3^- and NH_4^+ uptake rates with DIN:P.

Figure 6. Turnover time for the NO₃⁻ substrate, when small phytoplankton are the only consumers, in the sampling locations in the Arctic Ocean.

Figure 7. Turnover times for the NH₄⁺ substrate, when small phytoplankton are the only consumers, in the sampling locations.

Figure 8. Quantum C Yield of small phytoplankton in the sampling locations.

Figure 9. Quantum N yield of small phytoplankton in the sampling locations.
