10 Abstract

11 The colonization by a large number of sea animal, including penguins and seals, plays an
12 important role in the nitrogen cycle of the tundra ecosystem in coastal Antarctica. However, little
13 is known about the effects of sea animal colonization on ammonia-oxidizing archaea (AOA) and
14 bacteria (AOB) communities involved in nitrogen transformations. In this study, we chose active
15 seal colony tundra soils (SS), penguin colony soils (PS), adjacent penguin-lacking tundra soils
16 (PL), tundra marsh soils (MS), and background tundra soils (BS), to investigate the effects of sea
17 animal colonization on the abundance, activity, and diversity of AOA and AOB in maritime
18 Antarctica. Results indicated that AOB dominated over AOA in PS, SS, and PL; whereas AOB
19 and AOA abundances were similar in MS and BS. Penguin or seal activities increases the
20 abundance of soil AOB *amoA* genes, but reduced the abundance of AOA *amoA* genes, leading to
21 very large ratios (1.5×10^2 to 3.2×10^4) of AOB to AOA *amoA* copy numbers. Potential ammonia
22 oxidation rates (PAOR) were significantly higher ($P = 0.02$) in SS and PS than in PL, MS, and
23 BS, and were significantly positively correlated ($P < 0.001$) with AOB *amoA* gene abundance.
24 The predominance of AOB over AOA and their correlation with PAOR suggested that AOB were
25 more important in the nitrification in animal colony soils. Sequence analysis for gene clones
26 showed that AOA and AOB in tundra soils were from the *Nitrososphaera* and *Nitrospira*
27 lineages, respectively. Penguin or seal activities led to a predominance of AOA phylotypes related
28 to *Nitrososphaera* cluster I and AOB phylotypes related to *Nitrospira* clusters I and II, but very
29 low relative abundances in AOA phylotypes related to cluster II, and AOB phylotypes related to
30 cluster III and IV. The differences in AOB and AOA community structures were closely related

31 to soil biogeochemical processes under the disturbance of penguin or seal activities: soil C:N
32 alteration and sufficient input of NH_4^+ -N and phosphorus from animal excrements. The results
33 significantly enhanced the understanding of ammonia-oxidizing microbial communities in tundra
34 environment of maritime Antarctica.

35 **Keywords:** Antarctic tundra, AOA, AOB, Marine animals, Nitrification, Microbial diversity

36 1 Introduction

37 Nitrification, the oxidation of ammonia into nitrate through nitrite, plays a pivotal role in the
38 global biogeochemical nitrogen cycle (Nunes-Alves, 2016). As the first and rate-limiting step of
39 nitrification, ammonia oxidation (the aerobic oxidation of ammonia into nitrite) is performed by
40 phylogenetically and physiologically distinct groups of ammonia oxidizing archaea (AOA) and
41 ammonia oxidizing bacteria (AOB) (Belser and Schmidt, 1978; Könneke et al., 2005). The AOA
42 and AOB have been investigated using the *amoA* gene as a functional marker in a wide variety of
43 environments, including soils (Di et al., 2009; Gubry-Rangin et al., 2017; Leininger et al., 2006;
44 Ouyang et al., 2016; Shen et al., 2012), sediments (Li et al., 2015; Zheng et al., 2013), estuaries
45 (Dang et al., 2008; Mosier et al., 2008; Santoro et al., 2011), oxic and suboxic marine water
46 column (Baker et al., 2012; Bouskill et al., 2012), plateau permafrost (Zhang et al., 2009; Zhao et
47 al., 2017), and in sub-arctic and arctic soil (Alves et al., 2013; Daebeler et al., 2017). Results
48 indicated that the relative abundance and functional importance of AOA vs. AOB vary greatly in
49 natural ecosystems. Environmental drivers, including substrate concentration, oxygen availability,
50 pH, and salinity, might be responsible for the different AOA and AOB abundances and distribution
51 (Alves et al., 2013; Bouskill et al., 2012; Le Roux et al., 2008; Wang et al., 2015). The abundance,
52 diversity, and activity of ammonia-oxidizers have been explored in tundra soils of Antarctic
53 Peninsula (Jung et al., 2011; Yergeau et al., 2007), the Antarctic Dry Valleys (Ayton et al., 2010;
54 Magalhães et al., 2014; Richter et al., 2014), and in the Antarctic coastal waters (Kalanetra et al.,
55 2009; Tolar et al., 2016). However, there is still a large gap in our understanding of factors that

56 control AOA *versus* AOB prominence, and the relationships between nitrification rates and
57 ammonia-oxidizer dynamics need to be explored in the Antarctic.

58 In maritime Antarctica, a large number of sea animals, such as penguins or seals, settle on
59 coastal ice-free tundra patches. Tundra vegetation including mosses, lichens, and algae, penguin
60 colonies, and their interactions, form a special ornithogenic tundra ecosystem (Tatur et al., 1997).
61 The soil biogeochemistry of an ornithogenic tundra ecosystem has become a research hotspot
62 under the penguin-activity disturbance (Otero et al., 2018; Riddick et al., 2012; Simas et al., 2007;
63 Zhu et al., 2013, 2014). Previous studies indicated that sea animals significantly affect the tundra
64 N and P cycles (Lindeboom et al., 1984; Simas et al., 2007; Zhu et al., 2011), and the total N and
65 P excreted by seabird breeders and chicks are 470 Gg N yr⁻¹ and 79 Gg P yr⁻¹ in Antarctica and
66 the Southern Ocean, accounting for 80% of the N and P from total global seabird excreta (Otero
67 et al., 2018). Uric acid is the dominant N compound in penguin guano, and during its
68 mineralization, different N forms, such as NH₃, NH₄⁺, and NO₃⁻, can be produced via
69 ammonification, nitrification, and deposition, following the changes in soil pH and the C:N ratio
70 (Blackall et al., 2007; Otero et al., 2018; Riddick et al., 2012). The alteration of soil
71 biogeochemistry under the sea animal -activity disturbance might have an impact on the
72 abundance and diversity of the AOA and AOB involved in the nitrogen cycle. Increased bacterial
73 abundance, diversity, and activity have been detected in penguin or seal colony soils (Ma et al.,
74 2013; Zhu et al., 2015). Penguin or seal colonies have been confirmed as strong sources for
75 greenhouse gas N₂O (Zhu et al., 2008, 2013), a by-product of microbial ammonia oxidation

76 (Santoro et al., 2011). However, the effects of sea animal colonization on AOA and AOB
77 community structures have not been thoroughly investigated in the maritime Antarctic tundra.

78 In the present study, we investigated the abundance, activity, and diversity of soil AOA and
79 AOB in five tundra patches, including a penguin colony, a seal colony, the adjacent animal-lacking
80 tundra, tundra marsh, and background tundra, where soil biogeochemical properties were
81 subjected to the differentiating effects of sea animal activities. Our objectives were (a) to examine
82 the abundance, diversity, and community structure of soil AOA and AOB using the *amoA* gene as
83 a functional marker; (b) to investigate potential links between *amoA* gene abundance, AOA and
84 AOB community structures, activity, and environmental variables; and (c) to assess the relative
85 contribution of these two distinct ammonia-oxidizing groups to nitrification.

86 **2 Materials and methods**

87 **2.1 Study area**

88 The study area is located on the Fildes Peninsula and Ardley Island in the southwest of King
89 George Island (Fig. 1), having an oceanic climate characteristics. Mean annual air temperature is
90 about -2.5 °C, with the range of daily mean temperature from -26.6 to 11.7 °C, and mean annual
91 precipitation is about 630 mm, mainly in the form of snow. The Fildes Peninsula (about 30 km²
92 area) is a host to important sea animal colonies. Based on annual statistical data, the total of over
93 10,700 sea animals colonize this peninsula in the austral summer. On the western coast are
94 established seal colonies including elephant seal (*Mirounga leonine*), weddell seal (*Leptonychotes*
95 *weddellii*), fur seal (*Arctocephalus gazella*) and leopard seal (*Hudrurga leptonyx*) (Sun et al.,

96 2004). Ardley Island, with an area of 2.0 km in length and 1.5 km in width, is connected with the
97 Fildes Peninsula via a sand dam. This island belongs to an important Ecological Reserve for
98 penguin populations in western Antarctica. A great majority of breeding penguins, including
99 Adélie penguins (*Pygoscelis adeliae*), Gentoo penguins (*Pygoscelis papua*), and Chinstrap
100 penguins (*Pygoscelis antarctica*), colonized on the east of this island in the austral summer. Seal
101 excrements or penguin droppings rich in nitrogen and phosphorus were transported into local
102 tundra soils by ice-snow melting water during the breeding period (Sun et al., 2000, 2004). Mosses
103 and lichens dominate local vegetation. However, the vegetation is almost absent in penguin or
104 seal colonies because of overmanuring and animal trampling. More detailed description about the
105 study area can be found in Zhu et al. (2013).

106 **2.2. Tundra soil collection**

107 In the summer of 2014/2015, soil samples were collected from the following tundra patches,
108 as illustrated in Fig. 1:

109 (i) Penguin colony and penguin-lacking tundra sites: The tundra on Ardley Island was
110 categorized into three areas from the east to west according to the distance to the penguin nesting
111 sites (i.e., the intensity of penguin activity): The eastern active penguin colony with nesting sites,
112 PS (i.e., high penguin-activity area) where penguins have the highest density and high frequency
113 presence during the breeding period; the adjacent penguin-lacking tundra areas, PL (i.e., low
114 penguin-activity areas) in the middle of Ardley Island where penguins occasionally wander and
115 have a typically low density; and the western tundra marsh, MS, moderately far from penguin
116 nesting sites (i.e., a slight penguin-activity area) where penguins rarely frequent the sites. In total,

117 fourteen soil samples were collected from Ardley Island to study the effects of penguin
118 colonization on the abundance, activity, and community structures of soil AOA and AOB.
119 Specifically, samples PS1–PS5 were collected sequentially from the center of the colony in the
120 PS. Samples PL1–PL4 and MS1–MS5 were randomly collected in the PL and MS. (ii) The seal
121 colony and its adjacent tundra sites, SS: These sites are on the western coast of the Fildes
122 Peninsula. According to the distance to seal wallows (i.e., the intensity of seal activity), samples
123 SS1–SS5 were collected in sequence to investigate the effects of seal colonization. Site SS1 was
124 closest to the seal colony (i.e., a high seal-activity site), whereas SS5 was the farthest from the
125 seal colony (i.e., a low seal-activity site). (iii) Background tundra sites, BS: Three soil samples
126 were collected from an upland tundra with about 40 m a.s.l. and the distribution of no sea animal
127 around. The tundra surface is covered with mosses or lichens with a 10–15 cm organic clay layer
128 (Zhu et al., 2013).

129 At each sampling site, soil was collected aseptically using a clean scoop from the top 5–10 cm
130 at the four corners of a 1 m² subarea, and combined into one sample. Appropriate precautions
131 were taken to avoid cross-site or human-made contamination. Immediately after collection, each
132 sample was divided into two portions: one was stored in sterile plastic containers at –80 °C for
133 the analysis of the microbial community structures, and the other portion was stored at close to
134 the *in situ* temperature to determine the geochemical characteristics and potential ammonia
135 oxidation rates. All of the analyses were conducted within one month.

136 2.3. General analysis of soil characteristics

137 Soil pH was determined by mixing the soil and 1 M KCl solution (1: 3 ratio). Soil moisture
138 was measured by oven drying at 105 °C to a constant weight. Total carbon (TC), total nitrogen
139 (TN) and total sulfur (TS) contents in the soils were determined through a CNS analyzer (vario
140 MACRO, Elementar, Germany). The samples were digested in Teflon tubes using HNO₃-HCl-
141 HF-HClO₄ digestion at 190 °C, and total phosphorus (TP) was determined using ICP-OES (Perkin
142 Elmer 2100DV, Waltham, MA, USA). The NO₃⁻-N, NO₂⁻-N, and NH₄⁺-N concentrations were
143 determined through a continuous flow analyzer (Skalar, Netherlands) (Gao et al., 2018; Zhu et al.,
144 2011).

145 2.4. Measurement of soil ammonia oxidation rate

146 Potential ammonia oxidation rate (PAOR) in tundra soil was determined using the chlorate
147 inhibition method (Kurola et al., 2005; Xia, 2007). Sodium chlorate was used to inhibit NO₂⁻ from
148 being oxidized into NO₃⁻. Briefly, 5 g fresh tundra soil was incubated in 20 ml of 1 mM
149 phosphate-buffered saline with 1 mM of (NH₄)₂SO₄ and NaClO₃ in the dark at 15 °C. After
150 moderately shaking for 24 h, the 5 ml of 2 M KCl was used to extract the nitrite. The optical
151 density for the supernatant after centrifugation was determined spectrophotometrically at 540 nm.
152 The standard curve obtained from NaNO₂ (0–2.5 μmol l⁻¹) was used to calculate the PAOR in the
153 tundra soils.

154 2.5. DNA extraction and gene amplification (PCR)

155 Genomic DNA was extracted from 0.25 g of homogenized tundra soils using PowerSoil™
156 DNA Isolation Kit (Mo Bio, Carlsbad, CA, USA) as described in manufacturer's protocol. The
157 extracted DNA was eluted in 50 µl of elution buffer, quantified by a Nanodrop-2000
158 Spectrophotometer (Thermo Scientific, Waltham, MA, USA), and stored at -20 °C. AOA *amoA*
159 gene fragments (635 bp) were amplified using the primers Arch-amoAF (5'-
160 STAATGGTCTGGCTTAGACG-3') and Arch-amoAR (5'-GCGGCCATCCATCTGTATGT-3')
161 (Francis et al., 2005). The *amoA* gene fragment (491 bp) of β-proteobacterial AOB, which
162 represents known AOB in soil, was amplified using the primer set composed of amoA-1F (5'-
163 GGGGTTTCTACTGGTGGT-3') and amoA-2R (5'-CCCCTCKGSAAAGCCTTCTTC-3')
164 (Rotthauwe et al., 1997). All PCR reactions were performed using Taq PCR Master Mix (Sangon
165 Biotech, Shanghai, China) in a total volume of 50 µl. PCR reactions were carried out with a
166 thermal profile of 5 min at 95 °C; 35 cycles of 94 °C for 30 s, 56 °C for AOA or 55 °C for AOB
167 for 45 s, 72 °C for 1 min; and a final 5-min extension cycle at 72 °C (Zheng et al., 2014).
168 Subsequently, the amplification products were visualized by electrophoresis on 1.0 % agarose gels.

169 2.6. Sequencing and phylogenetic analysis

170 The amplification products were sent to Sangon Company (Shanghai, China) for purification,
171 cloning and sequencing (Zheng et al., 2014). The sequences were edited using DNASTAR
172 (DNASTAR, Madison, WI, USA), and then aligned by muscle using the UPGMB clustering
173 method with the ClustalX program. The sequences with 97% identity were grouped into one OTU
174 (operational taxonomic unit) using the mothur program (version 1.23.0) by the furthest neighbor

175 approach (Schloss et al., 2009). The closest reference sequences were identified at NCBI
176 (<http://www.ncbi.nlm.nih.gov/BLAST/>) using the BLASTn tool (Madden, 2002), and
177 phylogenetic trees were constructed by the neighbor-joining method using the Molecular
178 Evolutionary Genetics Analysis (MEGA) software (version 5.03, <https://www.megasoftware.net/>).
179 The sequences reported in this study have been deposited in GenBank under accession unumbers
180 MH318029 to MH318568 and MH301331 to MH302505.

181 **2.7. Quantitative real-time PCR**

182 The AOB and AOA *amoA* gene copy numbers for tundra soils were determined in triplicate
183 using quantitative real-time PCR (qPCR) on an ABI 7500 Sequence Detection System (Applied
184 Biosystems). The specific details were given by Zheng et al. (2014). The strong linear inverse
185 relationship confirmed the consistency of the qPCR assay between the threshold cycle and the log
186 value of gene copy numbers ($R^2 = 0.997$ for AOA; $R^2 = 0.999$ for AOB). The amplification
187 efficiencies for AOA and AOB were 99.8 % and 90.4 %, respectively. Melting curve analysis had
188 only one observable peak at a melting temperature (T_m) (84.9 °C for AOA and 89.6 °C for AOB)
189 (Fig. S1 in Supplementary Material). Negative controls were subjected to exclude any possible
190 carryover or contamination in all experments.

191 **2.8. Statistical analysis**

192 The Shannon–Weiner Index, Simpson Index and the richness estimator Chao 1 were calculated
193 by the mothur program (version 1.23.0, Schloss et al., 2009). The coverage was the percentage of
194 the number of observed OTUs divided by the Chao 1 (Table S1). The Kruskal–Wallis test and

195 Wilcoxon signed rank test were conducted for the comparison between *amoA* gene abundance and
196 PAOR from five tundra patches using SPSS Statistics 17 (IBM Corp, Armonk, NY, USA).
197 Correlations between ammonia-oxidizer gene abundance, PAOR and environmental variables
198 were obtained by Spearman Correlation Analysis. The relationships between the ammonia-
199 oxidizer community structure and environmental variables were explored using canonical
200 correspondence analysis (CCA) in the software Canoco for windows (version 4.5; Microcomputer
201 Power, Ithaca, NY, USA), because the maximum gradient length of both AOA and β -AOB was
202 longer than four SD (AOA: 4.406; AOB: 18.326). All environmental parameter values were
203 transformed into $\ln(x+1)$ before statistical analyses. The OTU richness (defined at 3% distance)
204 served as the species input and several simulations of manual forward selection were performed
205 with 499 Monte Carlo permutations to build the optimal models. The scaling in the final CCA
206 biplots was focused on inter-sample relations.

207 **3 Results**

208 **3.1. Soil chemistry and sea animal activities**

209 Almost all the tundra soils were slightly acidic, and the mean pH ranged from 5.3 to 6.6 at
210 each tundra patch (Table 1). In penguin or seal colony tundra soils, PS and SS, soil properties
211 including TC, TN, TS, TP, NH_4^+ -N and NO_3^- -N levels showed high heterogeneity due to the
212 deposition of penguin or seal excreta. In the seal colony tundra soils on Fildes Peninsula, the
213 highest TC, TN, TP, TS, and NH_4^+ -N levels occurred at the sites (SS1-2) close to the seal wallows.
214 In the tundra soils on Ardley Island, the highest TP, TS, and NH_4^+ -N levels occurred in the soils

215 close to the eastern penguin nesting sites (PS1-5). PS and SS had generally lower C:N ratios than
216 the penguin-lacking tundra soils (PL), tundra marsh soils (MS), and background tundra soils (BS).
217 Soil mean TN, TS and NH_4^+ -N levels were higher in PS, SS, PL, and MS than in BS. Soil NH_4^+ -
218 N contents were 1–2 orders of magnitude higher in PS and SS than in PL, MS, and BS, with the
219 means of 176.9 and 137.6 mg NH_4^+ -N kg^{-1} , respectively. The highest NO_3^- -N contents occurred
220 in SS. Phosphorus levels were significantly greater ($P < 0.05$) in PS (10.6–32.9 mg g^{-1}) than in
221 other types of tundra soils (mean < 6.0 mg g^{-1}). Overall, penguin or seal activities altered the local
222 soil biogeochemical properties through the deposition of their excreta, leading to generally low
223 C:N ratios in tundra soils.

224 3.2. Gene abundances under sea animal colonization

225 The abundance of the AOB *amoA* gene was significantly higher (by approximately 2–4 orders
226 of magnitude) than that of the AOA *amoA* gene (Wilcoxon test, $n = 22$, $P = 0.002$) in the penguin
227 and seal colony and the adjacent tundra soils, PS, SS, and PL. However, the abundances of the
228 *amoA* gene were similar in the MS and BS soils (Fig. 2a). Overall, the abundances of AOB and
229 AOA *amoA* genes were significantly negatively correlated ($r = -0.93$, $P = 0.002$) across all the
230 tundra sites (Fig. S2). The AOA *amoA* gene abundances showed a heterogeneous distribution
231 among the different tundra patches, and they were two orders of magnitude lower in PS and SS
232 relative to those in BS and MS. The maximal AOA *amoA* gene abundance appeared in BS,
233 followed by MS and PL, whereas the PS and SS soils had the lowest AOA *amoA* gene abundances.
234 The log values of soil AOA *amoA* gene abundances showed a significant positive correlation

235 ($r=0.52$, $P < 0.001$) with C:N ratios (Fig. 3a), but their abundances showed a significant negative
236 correlation with NH_4^+ -N contents ($r= -0.52$, $P = 0.013$) (Table 2).

237 Unlike the AOA *amoA* genes, AOB *amoA* gene abundances showed the opposite distribution
238 pattern. The AOB *amoA* gene abundances were significantly higher (by approximately 2–3 orders
239 of magnitude) in PS and SS compared with those in MS and BS (Fig. 2a). The log values of soil
240 AOB *amoA* gene abundances showed a significant negative correlation with C:N ratios ($r= -0.71$,
241 $P < 0.001$) (Fig. 3b), but their abundances showed a significant positive correlation with NH_4^+ -N
242 ($r=0.53$, $P < 0.05$) and TP ($r=0.47$, $P < 0.05$) (Table 2). The ratios of AOB to AOA *amoA* copy
243 numbers were strongly affected by animal activities, and were much higher in PS and SS than in
244 PL, MS, and BS (Fig. 2b; Kruskal–Wallis test, $\chi^2 = 18.2$, $P = 0.01$). Their ratios showed significant
245 positive correlation with NH_4^+ -N contents ($r=0.62$; $P < 0.01$) and TP ($r=0.43$, $P < 0.05$) (Table 2),
246 but significant negative correlation with the C:N ratios ($r= -0.79$; $P < 0.001$) (Fig. 3c). Overall,
247 penguin or seal activities, which were indicated by soil C:N ratios, significantly increases the
248 abundance of soil AOB *amoA* genes, but reduced the abundance of AOA *amoA* genes, leading to
249 very large ratios (1.5×10^2 to 3.2×10^4) of AOB to AOA *amoA* copy numbers in PS and SS.
250 However, the ratios varied only from 0.1 to 7.2 in BS and MS.

251 3.3 Potential ammonia oxidation rates under sea animal colonization

252 Potential ammonia oxidation rates (PAORs) ranged from 8.9 to 138.8 $\mu\text{g N kg}^{-1} \text{h}^{-1}$ in all the
253 soil samples (Table 1). The PAOR was slightly higher in SS (mean 76.1 $\mu\text{g N kg}^{-1} \text{h}^{-1}$) than in
254 PS (mean 64.7 $\mu\text{g N kg}^{-1} \text{h}^{-1}$), but significantly higher than in PL, MS, and BS (mean 12.0–21.8
255 $\mu\text{g N kg}^{-1} \text{h}^{-1}$). Overall, the PAOR was significantly higher in animal colony soils (mean 70.4 $\mu\text{g N kg}^{-1} \text{h}^{-1}$).

256 N kg⁻¹ h⁻¹ for SS and PS) than in non-animal colony soils (mean 15.7 μg N kg⁻¹ h⁻¹ for PL, MS,
257 and BS; Kruskal–Wallis test, $\chi^2=11.6$, P = 0.02) (Fig. 2c). The greatest POAR occurred at the
258 sites PS1 nearest the penguin nests (88.8 ± 2.7 μg N kg⁻¹ h⁻¹) and SS1 close to seal wallows (138.8
259 ± 0.8 μg N kg⁻¹ h⁻¹). The PAOR followed the distribution changes of AOB *amoA* gene abundances,
260 but showed the opposite trend to the AOA *amoA* gene abundances. A significant positive
261 correlation ($r^2 = 0.77$, P < 0.001) was observed between the PAOR and the AOB *amoA* gene
262 abundance when the data from all the tundra patches were combined, whereas no correlation
263 occurred between PAOR and AOA *amoA* gene abundance (Fig. 4). The AOB dominance over
264 AOA in the abundance in PS, SS and PL and their correlation with the PAOR suggested that AOB
265 populations might contribute more to the PAOR than the AOA populations in penguin or seal
266 colony. In addition, PAOR significantly negatively correlated with soil C:N ratios ($r = -0.73$,
267 P < 0.001) (Fig. 3d), but significantly positively correlated with TS contents ($r = 0.47$, P < 0.05) and
268 TP contents ($r = 0.43$, P < 0.05) (Table 2).

269 **3.4. Community structure of AOA and AOB under sea animal colonization**

270 The PCR products were insufficient to construct the clone libraries for the AOA *amoA* gene
271 from SS and PS because of the low AOA abundance in the soils, as was the case with the AOB
272 *amoA* gene from MS and BS. Overall, 10 AOA and 14 AOB *amoA* gene clone libraries were
273 successfully constructed. The 543 AOA sequences and 1175 AOB quality sequences were
274 generated from the respective sites. Within each individual site, 1–6 AOA OTUs and 6–15 AOB
275 OTUs were identified, as defined by < 3% divergence in nucleotides. The AOA and AOB OTU
276 numbers for each library are presented in Table S1. These numbers might be higher if more clones

277 were sequenced, based on the rarefaction curves (Fig. S3 and Fig. S4). The diversity of the AOB
278 *amoA* was generally higher than that of AOA *amoA*, based on the indices of Shannon–Wiener and
279 Simpson. Specifically, the AOA *amoA* gene had higher diversity in PL and MS than in BS,
280 whereas the AOB *amoA* gene showed higher diversity in SS and PS compared with that in adjacent
281 animal-lacking tundra soils (Table S1).

282 The 543 AOA *amoA* gene sequences had 76–100% sequence similarity to each other, and 95–
283 100% identity with the corresponding top hit *amoA* sequences deposited in GenBank.
284 Phylogenetic tree showed that the AOA *amoA* sequences were grouped into 16 unique OTUs,
285 representing 100% of all the AOA *amoA* OTUs identified, and these sequences were affiliated
286 with two *Nitrososphaera* clusters (Fig. 5a): Cluster I had 11 OTUs and 264 clones, and 57.9% of
287 AOA *amoA* sequences were from PL, 41.3% from SS, and only 0.8% from MS. In Cluster II,
288 there are five unique OTUs and 279 clones, and 58.8% of them were from BS, 38.3% from MS,
289 and only 2.9% from PL. Almost all the AOA phylotypes retrieved from PL and SS were related
290 to *Nitrososphaera* cluster I, whereas the AOA phylotypes retrieved from MS and BS were
291 distributed in cluster II (Fig. S5a in Supplementary Material). Seal or penguin activities led to the
292 predominant existence of AOA phylotypes related to cluster I, but very low relative abundances
293 in AOA phylotypes related to cluster II, which were almost completely excluded in SS and PL.
294 Almost all AOA phylotypes in BS and MS were related to *Nitrososphaera* cluster II, whereas the
295 relative abundances of AOA phylotypes related to cluster I were very low or undetectable.

296 The 1175 AOB *amoA* gene sequences shared 87–100% sequence identity to each other, and
297 93–100% identity with the closest matched GenBank sequences. AOB phylogenetic tree showed

298 38 unique OTUs, representing 58.5% of all the AOB *amoA* OTUs identified, and they were
299 grouped into four *Nitrosospira* clusters according to the evolutionary distance of the phylogenetic
300 tree (Fig. 5b). Cluster I had 11 OTUs and 226 clones, and 67.7% of AOB *amoA* sequences were
301 from PS, 23.5 % from SS, 8.4% from PL, and only 0.4% from MS. There are 17 unique OTUs
302 and 521 clones in clusters II and III. The sources of the OTUs in cluster II were similar to those
303 of cluster I, with 69.8% from PS, 29.9% from SS, and 0.3% from PL. For cluster III, 79.2% of
304 the sequences were from PL, 19.8% from SS, and 1.0% from MS. Cluster IV had nine unique
305 OTUs and 370 clones from PL (50.0%), SS (36.8%) and MS (13.2%), respectively. Of all the
306 AOB phylotypes retrieved from PS were related to dominant *Nitrosospira* clusters I and II,
307 whereas AOB phylotypes related to cluster III and IV were completely excluded because of
308 penguin colonization (Fig. S5b). The AOB phylotypes retrieved from SS were distributed in
309 clusters I, II, III, and IV (16–38% for each cluster). Almost all the AOB phylotypes retrieved from
310 PL and MS were related to *Nitrosospira* clusters III and IV.

311 **3.5. Relationships of the ammonia-oxidizer community structure with environmental variables**

312 The relationships of the AOA and AOB communities with environmental variables were
313 analyzed using CCA. The environmental variables explained 62.1% of the total variance in the
314 AOA *amoA* genotype compositions, and 71.5% of the cumulative variance of the genotype-
315 environment relationships in the first two CCA dimensions (Fig. 6a). Overall, the AOA
316 community structures significantly correlated with C:N ($F=2.59$, $P=0.022$) and TC ($F=2.07$,
317 $P=0.048$) in tundra soils (Table 3), and the combination of the two factors explained 39.6% of the
318 variation. High soil C:N and TC concentrations increased the AOA richness in MS and BS.

319 Although other environmental parameters, including TP, pH, $\text{NH}_4^+\text{-N}$ and $\text{NO}_3^-\text{-N}$ were not
320 statistically significant ($P > 0.05$), these variables additionally explained 47.3% of the variation..
321 As illustrated in Fig. 6b, the first two dimensions explained 26.6% of the total variance in the
322 AOB compositions, and 54.3% of the cumulative variance of the AOB genotype-environment
323 relationships. The composition and distribution of AOB communities correlated significantly with
324 C:N ratios ($F=1.844$, $P=0.002$) and $\text{NH}_4^+\text{-N}$ ($F=1.823$, $P=0.002$), and the two factors combined
325 yielded 21.9% of total CCA explanatory power. The others including TP, $\text{NO}_3^-\text{-N}$ and pH
326 accounted for 27.1% of the variance. Penguin or seal activities significantly increased the AOB
327 richness in SS and PS through higher $\text{NH}_4^+\text{-N}$ and P input from sea animal excrements, whereas
328 AOB richness was closely related to the soil C:N in PL and MS.

329 **4 Discussion**

330 **4.1. Effects of sea animal colonization on AOA and AOB abundances**

331 In this study, soil AOA *amoA* gene abundances were two orders of magnitude lower in PS and
332 SS relative to BS and MS; however, AOB *amoA* gene abundances were approximately 2–3 orders
333 of magnitude higher in PS and SS than in MS and BS, indicating that sea animal activities
334 increased the AOB population size, but decreased AOA abundances in tundra soils (Fig. 2 and
335 Fig. 3). Overall, the AOA *amoA* gene abundances obtained here were similar to the abundance
336 range reported in the soils of the Antarctic Dry Valleys and arctic tundra soils; however, the AOB
337 *amoA* gene abundances were two to three orders of magnitude higher in PS and SS than in
338 Antarctic Dry Valleys (Alves et al., 2013; Magalhães et al., 2014). In contrast to previous studies

339 indicating that AOA were more abundant than AOB in some terrestrial or marine ecosystems
340 (Beman et al., 2008; Lam et al., 2007; Wuchter et al., 2006; Yao et al., 2011), and in soils from
341 Antarctic Peninsula (Jung et al., 2011), our qPCR estimates showed that the AOB *amoA* copy
342 numbers were much greater than those of AOA *amoA* in PS, SS and PL because of sea animal
343 activities. However, their abundances were very close to each other in BS and MS. The ratios of
344 AOB to AOA abundance were strongly affected by sea animal activities, which were indicated by
345 soil C:N ratios (Fig. 2c). A shift in the relative abundance of AOA and AOB recorded previously
346 for the Antarctic Dry Valleys, with a greater abundance of AOB compared with that of AOA for
347 Battleship Promontory and Miers Valley, and the reverse for Upper Wright Valley and Beacon
348 Valley (Magalhães et al., 2014). The results for PS, SS, and PL are also in agreement with those
349 detected in subglacial soils (Boyd et al., 2011).

350 The ratios of AOB to AOA showed significant correlations with C:N, $\text{NH}_4^+\text{-N}$, and TP when
351 all the data were combined in the five tundra patches (Table 2). This suggested that C:N, $\text{NH}_4^+\text{-N}$,
352 and TP are key factors when AOB *amoA* genes are much more abundant than AOA *amoA* genes.
353 In Antarctica, the productivity of terrestrial ecosystems is strongly limited because of the
354 extremely low nitrogen levels (Park et al., 2007). However, the physiochemical properties for
355 tundra soils were strongly influenced by the deposition of penguin or seal excreta under effects of
356 local microbes (Tatur et al., 1997). Sea animals provide considerable external N inputs for their
357 colony soils and adjacent tundra soils through direct input of their excreta and atmospheric
358 deposition via ammonia volatilization (Lindeboom, 1984; Sun et al., 2002; Blackall et al., 2007;
359 Zhu et al., 2011; Riddick et al., 2012). Like ammonium, P is typical elements in penguin guano

360 (Sun et al., 2000). Generally low C:N ratios and significantly elevated $\text{NH}_4^+\text{-N}$ and TP
361 concentrations occurred in PS and PL due to penguin or seal activities (Table 1). These conditions
362 might be more favorable for AOB, allowing high abundance of AOB *amoA*, which explains the
363 strong correlations between AOB abundances and C:N, $\text{NH}_4^+\text{-N}$, and TP in the sea animal colony
364 soils (Table 2). This agreed with the high bacterial abundance previously documented in penguin
365 or seal colony soils and ornithogenic sediments (Ma et al., 2013; Zhu et al., 2015).

366 The AOA abundance showed a significant negative correlation with $\text{NH}_4^+\text{-N}$ levels in tundra
367 patches (Table 2), indicating that AOA might better adapt to low NH_4^+ and oligotrophic
368 environments (Martens-Habbena et al., 2009; Stieglmeier et al., 2014). High $\text{NH}_4^+\text{-N}$
369 concentrations might partially inhibit AOA populations (Hatzenpichler et al., 2008). This result is
370 similar to that reported for some agricultural soils with increased fertilization, and grassland soils
371 with increased grazing (Fan et al., 2011; Prosser and Nicol, 2012; Pan et al., 2018), supporting the
372 conclusion that AOA and AOB generally inhabit different niches in soil, distinguished by the
373 NH_4^+ concentration and availability (Verhamme et al., 2011; Wessén et al., 2011).

374 **4.2. Effects of sea animal colonization on soil ammonia oxidation rates**

375 The PAOR ranged from 9 to 139 $\mu\text{g N kg}^{-1} \text{h}^{-1}$, lower than nitrification rates measured in most
376 agricultural soils (83–1875 $\mu\text{g N Kg}^{-1} \text{h}^{-1}$) (Fan et al., 2011; Ouyang et al., 2016; Daebeler et al.,
377 2017). One reason might be the selection of a 15 °C incubation temperature, which was lower
378 than the incubation temperatures used in other studies. Generally, the gross nitrification rate and
379 *amoA* abundance increased significantly when the incubation temperature was higher than 15 °C
380 (Daebeler et al., 2017; Zhao et al., 2014). Our measurements indicated that there were significant

381 differences ($P = 0.02$) in the PAOR across different tundra patches, and the PAORs in SS and PS
382 were about 10 times higher than those in BS and MS. A significant correlation was observed
383 between the PAOR and C:N, TP, and TS (Table 2). Overall, ammonia oxidation activity was
384 modulated by soil biogeochemical processes under the disturbance of penguin or seal activities:
385 generally low C:N ratios, and sufficient input of the nutrients TP, TS, and $\text{NH}_4^+\text{-N}$ from sea animal
386 excrements.

387 The AOB dominance over AOA in the abundance (Fig. 2b) and significant negative
388 correlation of AOA abundance with $\text{NH}_4^+\text{-N}$ levels (Table 2), indicated that AOB might play a
389 more important role in nitrification in tundra soils. In agreement with these results, AOB
390 dominated nitrification in the areas where it was easy to achieve nitrogen input, whereas the
391 relative contribution of AOA to nitrification was higher in the areas where the ammonium
392 concentration remained low (Fan et al., 2011; Sterngren et al., 2015). Moreover, the cell-specific
393 activity for AOB was 10 times higher than that for AOA due to the bigger cell size of AOB
394 (Hatzenpichler et al., 2012; Prosser and Nicol, 2012). Therefore, AOB might play a more
395 important role in nitrification in SS, PS, and PL with the input of $\text{NH}_4^+\text{-N}$ from penguin or seal
396 excrements.

397 In addition, AOA might play a role that cannot be ignored in MS and BS, just like the
398 prevalence of AOA among ammonia-oxidizers in Arctic soils (Alves et al., 2013; Daebeler et al.,
399 2017). AOB groups were mostly undetectable in the analysis of MS and BS. Although unknown
400 γ -AOB groups might not have been detected, the primer set used here covers the β -AOB groups
401 typically found in soils (Alves et al., 2013). The BS and MS were moderately far away from

402 penguin or seal colonies without the input of the nutrients from sea animal excrements, and their
403 substrates can be provided only through the mineralization of organic matter from local tundra
404 plants. The simple organic substrates and barren soil environment might favor AOA (Stopnišek
405 al., 2010; Habteselassie et al., 2013). Therefore AOA showed relatively high abundance in MS
406 and BS compared with PS and SS.

407 **4.3. Effects of sea animal colonization on genotypic diversity of soil AOA and AOB**

408 In this study, distinct AOA communities appear to inhabit different types of tundra patches,
409 depending on sea animal activities (Fig. 5a). It was difficult to amplify the AOA *amoA* gene from
410 SS and PS, whereas a high diversity of AOA *amoA* genes was observed in PL, MS and BS.
411 Phylogenetic analysis indicated that the AOA *amoA* sequences in Cluster I were from PL and
412 tundra soils close to seal wallows, while the sequences in Cluster II were from BS and MS (Fig.
413 S5). AOA in most extreme environments have lower levels of microbial diversity than benign
414 ecosystems because of the requirement for specific physiological adaptations, which allow
415 organisms to exploit the combination of physical and biochemical stressors (Cowan et al., 2015).
416 Detected OTUs in Cluster I had their closest matches mainly from the hyper-arid soils of Antarctic
417 dry valleys (Magalhães et al., 2014), wetland soils (Zheng et al., 2014), alpine meadow soils (Zhao
418 et al., 2017), and some agricultural soils (Glaser et al., 2010). Cluster II were more prevalent in
419 BS and MS, probably because of their stronger adaptation to barren soil environments. In cluster
420 II, the sequences were affiliated with sequences recovered from cold environments, including the
421 soils of Tibetan Plateau (Xie et al., 2014) and Icelandic grassland soils (Daebeler et al., 2012).
422 The compositions of soil AOA populations are likely not to be explained by single

423 physicochemical properties, and their community structures significantly correlated with tundra
424 soil C:N, and TC, which was consistent with previous studies (Glaser et al., 2010; Wessén et al.,
425 2011).

426 The AOB *amoA* gene generally had a higher diversity than AOA, similar to results in the
427 Antarctic Dry Valley soils (Magalhães et al., 2014). A high diversity of AOB *amoA* gene occurred
428 in SS, PS and PL compared to BS, indicating that penguin or seal activities had important effects
429 on AOB genotypic diversity. Phylogenetic analysis indicated that the sequences in clusters I and
430 II were mainly from PS and SS (Fig. 5b), and the detected OTUs in Cluster I had their closest
431 matches from mixed community culture systems, meadow to forest transect in Oregon Cascade
432 Mountains (Mintie et al., 2003), and Dutch agricultural soils (Silva et al., 2012a) and reservoir
433 sediments (Silva et al., 2012b). For Clusters III and IV, the sequences were predominantly from
434 PL and SS, and they were affiliated with sequences recovered from high altitude wetland (Yang
435 et al., 2014). Previous studies have shown that multiple environmental factors affected the AOB
436 communities (Dang et al., 2008; Mosier and Francis, 2008). In this study, the C:N ratios and NH_4^+ -
437 N concentrations seemed to be the most important factors influencing the AOB community
438 structure, which was in accordance with the results from different environments (Bouskill et al.,
439 2012; Jung et al., 2011; Li et al., 2015). Moreover, the TP also affected the AOB *amoA* community
440 compositions (Zheng et al., 2013). Therefore, the AOB community compositions were impacted
441 by the biogeochemical factors related to sea animal activities, such as low C:N ratios, and
442 sufficient supply of the nutrients NH_4^+ -N and TP from sea animal excreta.

443 **5 Conclusions**

444 The findings of this study concerning the abundance, activity, and diversity of tundra soil AOA
445 and AOB provide insights into microbial mechanisms driving nitrification in maritime Antarctica.
446 We confirmed the presence of AOA and AOB *amoA* genes in five different tundra patches, and
447 demonstrated that the spatial distribution heterogeneities of the tundra soil AOA and AOB
448 communities were driven by penguin or seal activities. The soil AOB *amoA* copy numbers were
449 generally higher than the AOA *amoA* copy numbers, following the higher PAOR in penguin or
450 seal colonies and their adjacent tundra, compared with that in the background tundra and marsh
451 tundra. Penguin or seal activities resulted in significant shift of soil AOA and AOB community
452 compositions. The diversity of the AOB *amoA* gene was greater in SS and PS than in PL and MS,
453 and the majority of the AOB sequences were closely related to *Nitrosospira*-like sequences. The
454 AOA *amoA* gene had higher diversity in PL and MS than in BS, and they were associated with
455 *Nitrososphaera* sequences recovered from barren soils. Soil AOB and AOA abundances, and their
456 community compositions, were related to soil biogeochemical processes under the sea animal-
457 activity disturbance, such as soil C:N alteration, and a sufficient supply of the nutrients NH_4^+ -N,
458 N and P from animal excreta. This study significantly enhanced the understanding of ammonia-
459 oxidizing microbial communities in tundra environment of maritime Antarctica.

Note: ND indicated that the soil sample was not determined.

Table 2. Spearman correlations (n=22) among ammonia oxidizer populations, the ratios of AOA: AOB abundances, potential ammonia oxidation rates (PAOR), and environmental variables in the soils of maritime Antarctic tundra.

	pH	Moisture	TC	TN	C/N	TS	TP	NH ₄ ⁺ -N	NO ₃ ⁻ -N	NO ₂ ⁻ -N
AOA (copies g ⁻¹)	0.331	-0.108	0.002	-0.243	0.373	-0.381	-0.195	-0.523*	-0.112	0.027
AOB (copies g ⁻¹)	-0.191	-0.293	-0.434*	-0.271	-0.748**	0.232	0.468*	0.526*	-0.261	-0.108
AOB/AOA	-0.274	-0.206	-0.337	-0.108	-0.720**	0.313	0.425*	0.622**	-0.117	-0.022
PAOR (µgN Kg ⁻¹ h ⁻¹)	0.221	-0.104	-0.185	0.032	-0.667**	0.468*	0.430*	0.307	-0.304	-0.138

Note: Significant correlations are indicated by * at the P=0.05 level, and ** at the P=0.01 level.

Table 3. Individual and combined contributions of soil biogeochemical properties to the AOA and AOB community structures in tundra patches.

	Soil properties	F	P	Individual contribution
AOA	C:N	2.593	0.022	21.5%
	TC	2.068	0.048	18.0%
	NO ₃ ⁻ -N	1.847	0.078	16.5%
	pH	1.458	0.144	13.5%
	TP	1.035	0.406	10.5%
	NH ₄ ⁺ -N	0.731	0.622	7.3%
	Combined effect of all factors			86.9%
AOB	C:N	1.844	0.002	11.6%
	NH₄⁺-N	1.823	0.002	11.5%
	TP	1.39	0.078	9.1%
	pH	1.383	0.066	9.0%
	NO ₃ ⁻ -N	1.161	0.258	7.7%
	Combined effect of all factors			48.9%

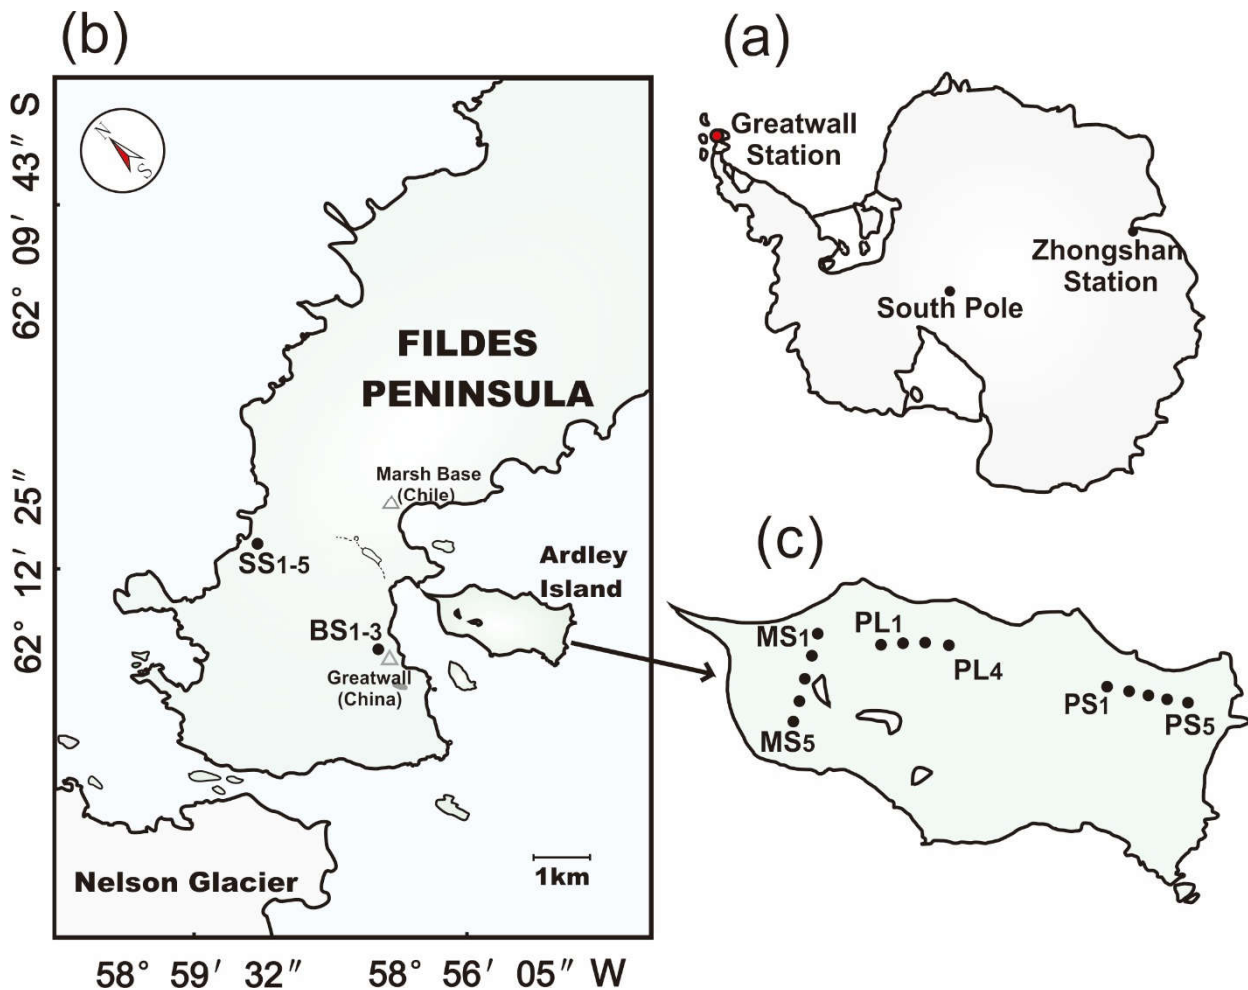

Figure 1. Study area and soil sampling sites. Panel (a), the red dot indicates the location of the investigation area in maritime Antarctica. Panel (b), location of the sampling sites on the Fildes Peninsula. The sampling soils from tundra patches included the active seal colony tundra soils SS (SS1–5) in the western coast of the Fildes Peninsula, and the background tundra soils on the upland areas (BS1–3). Panel (c), the location of the sampling sites on Ardley Island. The sampling soils from tundra patches included the western tundra marsh soils (MS1–5), the eastern active penguin colony tundra soils PS (PS1–5) and the adjacent penguin-lacking tundra soils PL (PL1–4). Note: The map was drawn using CorelDRAW X7 software (<http://www.corel.com/cn/>).

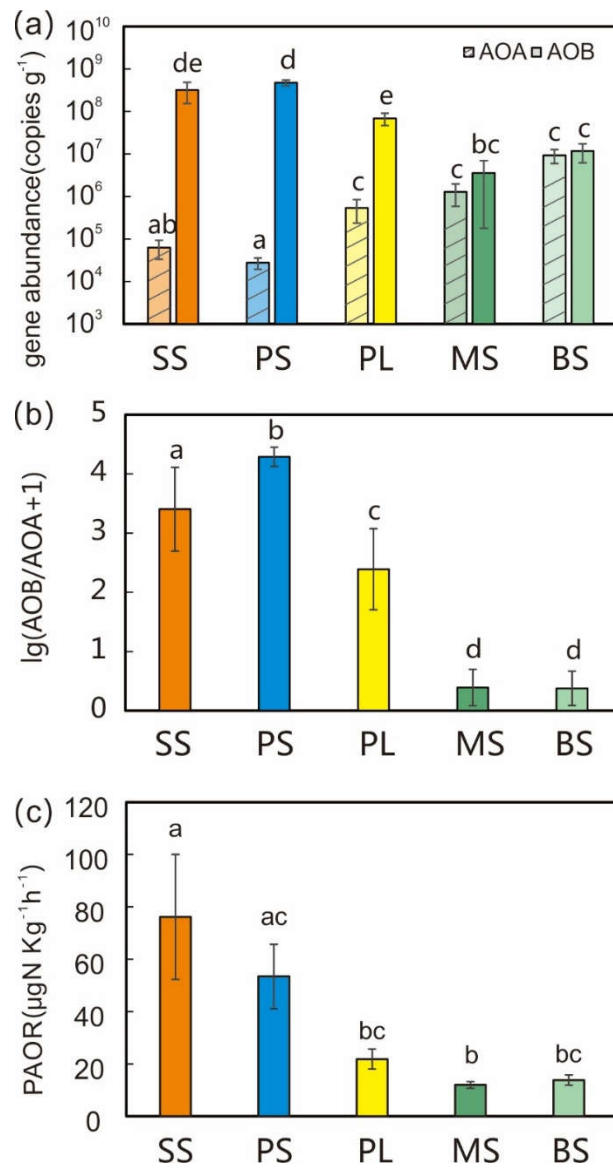

Figure 2. Comparisons of soil AOA and AOB *amoA* gene copy numbers (a), log ratio of AOB:AOA abundances (b), and potential ammonia oxidation rates (PAOR) (c) between five tundra patches. The error bars indicate standard deviations of the means.

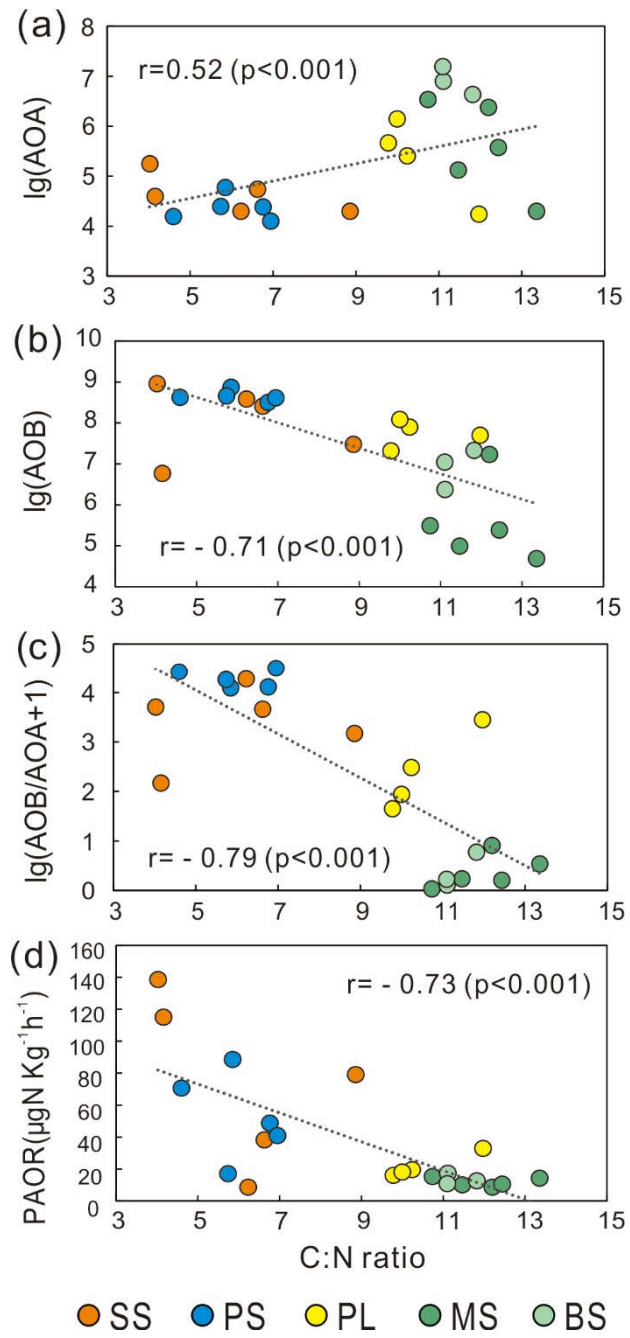

Figure 3. Effects of soil C:N alteration on AOA and AOB abundances, and potential ammonia oxidation rates (PAOR) at five tundra patches.

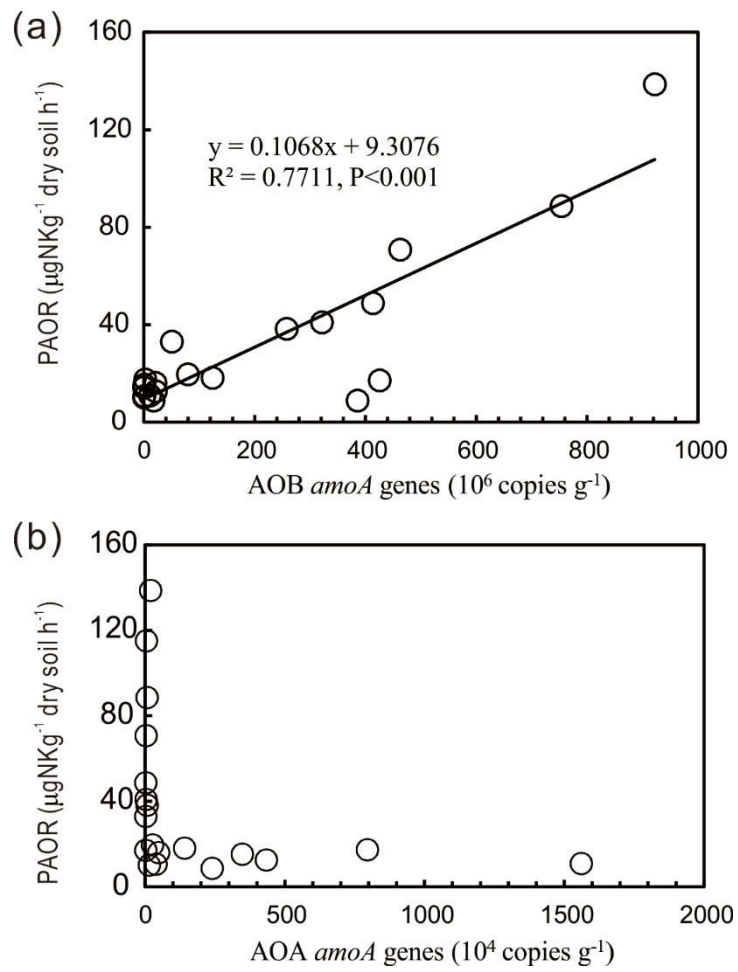

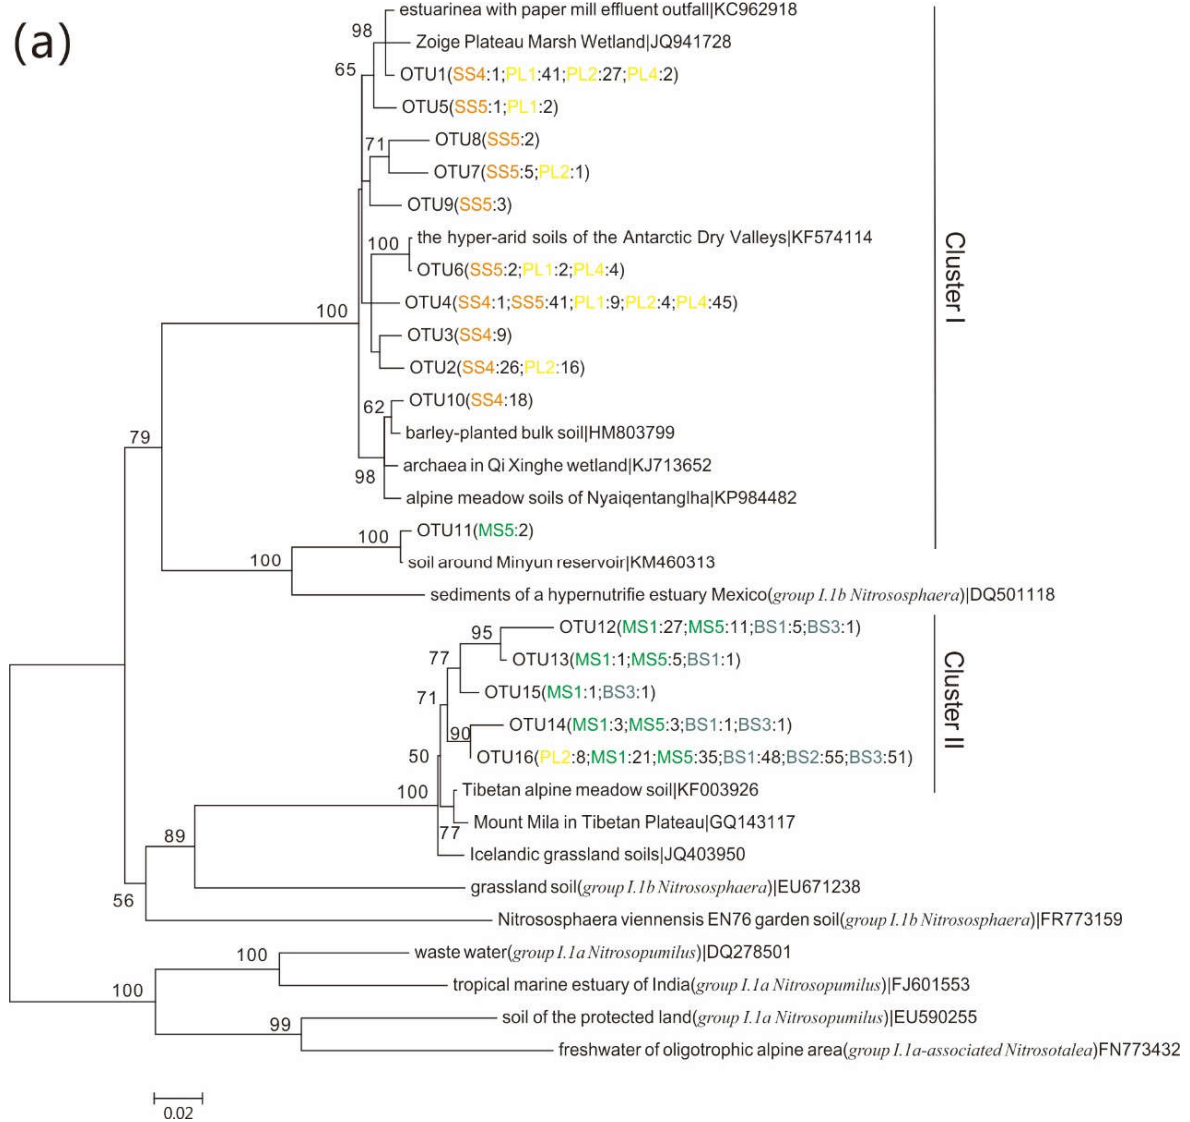

Figure 4. Correlation between potential ammonia oxidation rates (POARs) and AOA and AOB *amoA* gene copy numbers in tundra soils of maritime Antarctica.

Figure 5. Neighbor-joining phylogenetic tree of AOA *amoA* (a) and AOB *amoA* (b). The phylogeny is based on nucleotide sequences. Bootstrap values $\geq 50\%$ (of 1000 iterations) are shown near the nodes. GenBank accession numbers are shown for sequences from other studies. OTUs were defined at 97% similarity. Numbers in parentheses following each OTU indicate the number of sequences recovered from each sampling site.

(b)

0.02

Figure 6. Canonical correspondence analysis (CCA) ordination plots for the relationship between the AOA and AOB community structures with environmental variables. The circles with different colors represent the various sampling sites. The size of the circles corresponds to the OTU richness in individual samples. The black triangles represent amoA phylotypes. Environmental variables are represented by red arrows. The percentage of species-environment relation variance explained by the two principal canonical axes is represented close to the axes.
