8 **Abstract.** The breakdown of soil aggregates and the extraction of particulate organic matter
9 (POM) by ultrasonication and density fractionation is a method widely used in soil organic
10 matter (SOM) analyses. It has recently also been used for the extraction of microplastic from
11 soil samples. However, the investigation of some POM physiochemical properties and
12 ecological functions might be biased, if particles are comminuted during the treatment. In this
13 work, different types of POM, which are representative for different terrestrial ecosystems and
14 anthropogenic influences, were tested for their structural stability in face of ultrasonication in a
15 range of 0 to 500 J ml⁻¹. The occluded particulate organic matter (oPOM) of an agricultural
16 and forest soil as well as pyrochar showed a significant reduction of particle size at ≥ 50 J ml⁻¹
17 by an average factor of 1.37 ± 0.16 and a concurrent reduction of recovery rates by an average
18 of 21.7 ± 10.7 % when being extracted. Our results imply that ultrasonication causes an
19 imitated carry-over of POM to more strongly bound fractions or to the mineral-associated
20 organic matter (MOM) due to enhanced attraction to the mineral phase, which could e.g. lead
21 to a false estimation of physical stabilization. In contrast, neither fresh nor weathered
22 polyethylene (PE), polyethylene terephthalate (PET) and polybutylene adipate terephthalate
23 (PBAT) microplastics showed a reduction of particle size or the recovery rate after application
24 of ultrasound. We conclude that ultrasonication applied to soils has no impact on microplastic
25 size distribution and thus provides a valuable tool for the assessment of microplastics in soils
26 and soil aggregates.

27 **1 Introduction**

28 The mechanical disintegration of soil aggregates by use of ultrasonication following the
29 method of Edwards and Bremner (1967a) is widely used in the assessment of soil organic
30 matter (SOM) stability. This includes characteristics such as aggregate composition and
31 stability (Edwards and Bremner, 1967b), the constitution of SOM pools (Golchin et al., 1994),
32 the stabilization of SOM in forest ecosystems (Graf-Rosenfellner et al., 2016) and the
33 occlusive strength of particulate organic matter (POM) (Büks and Kaupenjohann, 2016).
34 Ultrasonication is also applied to assess quantities and qualities of anthropogenic
35 contaminants such as microplastics (Zhang and Liu, 2018; Zhang et al., 2018).

36 In studies on soil carbon pools, sonotrodes are applied to break down soil aggregates and
37 separate the free and occluded light fractions (fLF and oLF) from the heavy fraction (HF).
38 These operational fractions correspond largely to the free particulate organic matter (fPOM),
39 the occluded particulate organic matter (oPOM) and the mineral-associated organic matter
40 (MOM), which are assigned to the labile, intermediate and stable carbon pool, respectively,
41 and have turnover times of <1 year (labile) to several thousands of years (stable) (Lützow et
42 al., 2007). Furthermore, the extracted POM fractions may not only contain the natural but also
43 anthropogenic components such as microplastic. Its quantification and characterization is a
44 very topical task in the growing research on microplastic contamination of soils and requires a
45 high extractive performance. In addition, when optical methods are used to determine the size
46 and shape of the microplastic, the extraction should also cause the least possible damage to
47 the extracted material, because both attributes provide information about the source (Zhang
48 and Liu, 2018; Ding et al., 2020), the mobility within the soil pore space (O'Connor et al.,
49 2019) and the ingestibility of microplastic by soil organisms (Büks et al., in review).

50 The common method of ultrasonication is carried out with a piezo-electric converter, that uses
51 electric energy to generate axial vibration of a sonotrode, which is dipped into a flask
52 containing a fluid and a submerged soil sample. The oscillating sonotrode emits acoustic
53 pulses within the fluid. In front of the shock-waves the medium is compressed, and the
54 increased pressure causes an increased gas solubility. Behind the wave the medium relaxes
55 and the pressure drops below the normal level leading to an explosive outgassing (Ince et
56 al., 2001). This so called cavitation effect produces lots of exploding micro-bubbles between
57 particles and within cavities of the soil matrix generating very local pressure peaks of
58 200 to 500 atm accompanied by temperatures of 4200 to 5000 K (Ince et al., 2001). It
59 provokes the detachment of physiochemical bondings between soil primary particles and soil
60 aggregates and, thus, causes disaggregation. Depending on device type and settings, the
61 vibration frequency can vary up to 10000 kHz, but low frequencies around 20 to 100 kHz are
62 recommended for soil aggregate dispersion to avoid chemical alteration of OM, and the use of
63 40 kHz is very common. (Kaiser and Berhe, 2014; Graf-Rosenfellner et al., 2018)

64 As an artifact of the method, ultrasonication is known to provide mechanical and thermal
65 stress strong enough to comminute mineral particles at energy levels $>700 \text{ J ml}^{-1}$ (Kaiser and
66 Berhe, 2014). Also, the destructive influence on POM was tested in different studies and
67 appears even at energy levels much lower than 700 J ml^{-1} . Without application of a solid
68 mineral matrix, Balesdent et al. (1991) found $>60 \%$ of the POM in suspension comminuted
69 after application of 300 J ml^{-1} . Amelung and Zech (1999) treated natural soils with
70 0 to 1500 J ml^{-1} and performed a separation into size fractions of $<20 \mu\text{m}$, 20 to $250 \mu\text{m}$ and
71 $>250 \mu\text{m}$. At $\geq 100 \text{ J ml}^{-1}$ POM was transferred from the $>250 \mu\text{m}$ to the $<20 \mu\text{m}$ fraction. In a
72 similar manner, Yang et al. (2009) measured the mass and SOC content of sand, silt and clay
73 sized particle fractions in natural soils using an unconventional pulse/non-pulse
74 ultrasonication technique. The authors derived the comminution of POM at $>600 \text{ J ml}^{-1}$. Oorts
75 et al. (2005) added ^{13}C -enriched straw to natural soils and could show that larger amounts of
76 POM were redistributed at 450 J ml^{-1} when its degree of decomposition was higher. In
77 conclusion, those studies consistently found a comminution of POM by ultrasonic treatment,
78 which appears, however, at very different energy levels and is likely affected by the
79 aggregation regime (suspended without mineral matrix, added as fPOM, occluded within
80 natural soils), direct or indirect quantification of POM and the type of POM.

81 The aim of this work was to test under standardized conditions how susceptible different
82 POMs are to comminution by ultrasonic treatment. We embedded three POMs (farm oPOM,
83 forest oPOM and pyrochar, applied as an analog for soil black carbon and biochar
84 amendments) and also six differently weathered microplastics (fresh and weathered low-
85 density polyethylene (LD-PE), polyethylene terephthalate (PET) as well as polybutylene
86 adipate terephthalate (PBAT), a common biodegradable material) into a fine sand matrix.
87 Then, we treated these mixtures with 0, 10, 50, 100 and 500 J ml^{-1} , re-extracted the organic
88 particles with density fractionation and measured their recovery rates and particle size
89 distributions. The sand matrix was used only to simulate the influence of pore space on
90 cavitation and, thus, our simplified approach excluded broadly varying POM–mineral
91 interactions resulting from aggregation processes in natural soil samples. We hypothesized
92 the strongest comminution in case of the two oPOMs, that already started to decomposed
93 within their former natural soil matrix, and we were curious about the effect of ultrasonication
94 and artificial weathering on the structural stability of microplastic, which has not been studied
95 before.

96 **2 Material and methods**

97 **2.1 Preparation of POM**

98 The farm and forest oPOMs were extracted from air-dried soil aggregates of 630 to 2000 μm
99 in diameter sampled in 10 to 20 cm depth from an organic horticulture near
100 Oranienburg/Brandenburg (N 52° 46' 54, E 13° 11' 50, texture Ss, $C_{\text{org}}=4.9 \text{ g kg}^{-1}$, pH 5.8)
101 and a spruce/beechn mixed forest near Bad Waldsee/Baden-Württemberg (N 47° 50' 59,
102 E 9° 41' 30, texture Sl4, $C_{\text{org}}=7.3 \text{ g kg}^{-1}$, pH 3.4), respectively. The extraction was performed
103 by use of a density fractionation in 1.6 g cm^{-3} dense sodium polytungstate (SPT) solution: In
104 12-fold replication, 120 ml of SPT solution were added to 30 g of aggregates in a 200 ml PE
105 bottle. The sample was stored for 1 h to allow the SPT solution to infiltrate the aggregates and
106 was then centrifuged at 3500 G for 26 min. The floating free particulate organic matter (fPOM)
107 was removed by use of a water jet pump and discarded. The remaining sample was refilled to
108 120 ml with SPT solution and sonicated for 30 sec ($\approx 10 \text{ J ml}^{-1}$) by use of a sonotrode
109 (Branson© Sonifier 250) in order to flaw the structure of macroaggregate ($>250 \mu\text{m}$). Then,
110 centrifugation and removal of the oPOM were executed as for the fPOM. The gained oPOM
111 was filtered off with an $0.45 \mu\text{m}$ cellulose acetate membrane filter, washed 3 to 5 times with
112 200 ml deionized water within the filter device until the rinse had an electrical conductivity of
113 $<50 \mu\text{S cm}^{-1}$, removed from the filter by rinsing with deionized water, collected and gently
114 dried for 48 h at 40°C . At the end, the oPOMs were sieved to $2000 \mu\text{m}$, long-shaped residues
115 were cut by a sharp knife, sieved again and pooled to one oPOM sample. The pyrogenic char
116 sample (made from pine wood, pyrolysed at 850°C for 0.5 h by PYREG® GmbH) was dried for
117 24 h at 105°C , ground in a mortar and sieved to $<630 \mu\text{m}$. The microplastics (LD-PE, PET
118 and PBAT) were made from plastic films by repeated milling (Fritsch Pulverisette 14) with
119 liquid nitrogen and sieved to $<500 \mu\text{m}$. Then, half of each sample was weathered for 96 h at
120 38°C , 1000 W m^{-2} (solar spectrum, 280 to 3000 nm) and a relative air humidity of 50 %
121 following DIN EN ISO 4892-2/3.

122 **2.2 Mechanical stress treatment**

123 In order to test their stability against ultrasonication, the nine POM types (farm and forest
124 oPOM and pyrochar as well as fresh and weathered LD-PE, PET and PBAT) were each
125 exposed in triplicates to different mechanical stress levels (0, 10, 50, 100 and 500 J ml^{-1}).
126 Therefore, 1 % w/w POM, and 0.5 % w/w in case of the oPOMs, were embedded into an acid-
127 washed and calcinated fine sand matrix, which simulates the soil mineral matrix. These
128 artificial soils (each 20 g) were stored in 100 ml of 1.6 g cm^{-3} dense SPT solution for 1 h in
129 200 ml PE bottles, that did not show measurable release of plastic fragments due to
130 sonication in preliminary tests with a pure fine sand matrix (data not shown). Mechanical
131 stress was applied by use of a sonotrode (Branson© Sonifier 250) as described by Büks and

132 Kaupenjohann (2016). The sonication times corresponding to 0, 10, 50, 100 and 500 J ml⁻¹
133 were determined by means of the sonotrode's energy output calculated following North
134 (1976). After the ultrasonic treatment, samples were centrifuged at 3500 G for 26 min. The
135 floated POM was removed by use of a water-jet pump, separated and cleaned by rinsing with
136 deionized water on a 0.45 μm cellulose acetate membrane filter until the electrical
137 conductivity of the rinse went below 50 μS cm⁻¹, and then lyophilized.

138 **2.3 Determination of recovery rates**

139 After lyophilization, the recovery rate $R = m_t m_0^{-1}$ was determined by weighing as the ratio of
140 the recovered POM mass after treatment (m_t) to the initial POM mass (m_0) for all POM types
141 and energy levels. The recovery rates for each replicate were plotted over the energy levels
142 to show initial rates at 0 J ml⁻¹ and the influence of the mechanical stress treatment increasing
143 to 500 J ml⁻¹ (Fig. 1). The recovery rate at a certain energy level is assumed significantly
144 different to the 0 J ml⁻¹ level, if a pairwise t-test results in a $p < 0.05$ (Table 1).

145 **2.4 Measurement of particle sizes**

146 All samples continued to be used for particle sizing. After pre-trials have shown that mainly
147 the hydrophobic particles (microplastics and pyrochar) coagulated in distilled water,
148 aggregation was avoided by suspension in 0.1 % w/v Tween© 20 detergent solution and
149 vortexing following Katija et al. (2017). About 100 mg of POM were suspended in 500 ml
150 0.1 % Tween© 20 solution and size classified with a QICPIC image analysis device
151 (Sympatec GmbH, Clausthal-Zellerfeld, Germany) using a modified method from Kayser et al.
152 (2019). Counts were grouped into 34 size classes from <5.64 μm to 1200–1826.94 μm and
153 plotted as cumulative histograms of each replicate and their mean values (Fig. 2a and 2b). As
154 the primary criterion for the reduction in particle size, the first 10 % and 50 % quantile
155 (median) values were compared by pairwise t-test between 0 J ml⁻¹ and each other energy
156 level, respectively. As particle size reduction could be significant but still marginal in case of a
157 low variance between parallels and and a low grade of comminution at the same time, the
158 averaged comminution factor (CF) was introduced. It is defined as

$$159 \quad CF = \frac{\sum_i \left(\frac{x_{0,i}}{x_i} \right)}{i} \quad (1)$$

160 with i the number of parallels, $x_{0,i}$ the quantile value of the 0 J ml⁻¹ energy level and x_i the
161 value of the compared energy level. A sample is then assumed significantly different to the
162 0 J ml⁻¹ control and not marginal, if the p -value given by the t-test is < 0.05 and the

163 comminution factor is >1.1 for the 10 % quantile, the median or both, while its standard
164 deviation is $sd < |CF - 1|$. (Table 2)

165 3 Results

166 3.1 Resulting recovery rates

167 All microplastic samples (LD-PE, PET and PBAT) show a constantly high recovery rate of
 168 about 97.1 ± 2.5 % in average over the whole range of applied energy levels. In sharp contrast,
 169 all soil derived POMs (farmland, forest) and pyrochar were decreasingly recovered along with
 170 increasing energy levels and had significant differences to the 0 J ml^{-1} treatment at $\geq 10 \text{ J ml}^{-1}$,
 171 $\geq 100 \text{ J ml}^{-1}$ and $\geq 100 \text{ J ml}^{-1}$, respectively. (Fig. 1 , Table 1)

Figure 1: Recovery rates of natural POMs (left) and microplastics (right) after ultrasonic treatment with 0, 10, 50, 100 and 500 J ml^{-1} ($n=3$). The (w) marks weathered plastics.

Table 1: Recovery rates of natural POMs and microplastics from after ultrasonic treatment with 0, 10, 50, 100 and 500 J ml^{-1} ($n=3$). The (w) marks weathered plastics, mv mean value and sd standard deviation. Bold numbers are significantly different from the 0 J ml^{-1} treatment by $p < 0.05$.

sample	recovery rate [%w/w]									
	0 J ml ⁻¹		10 J ml ⁻¹		50 J ml ⁻¹		100 J ml ⁻¹		500 J ml ⁻¹	
	mv	sd	mv	sd	mv	sd	mv	sd	mv	sd
farm oPOM	95.0 ± 2.3		80.8 ± 4.5		73.2 ± 6.1		72.3 ± 2.8		51.6 ± 7.2	
forest oPOM	89.3 ± 5.4		79.0 ± 5.1		76.9 ± 8.4		67.8 ± 3.6		48.7 ± 5.4	
pyrochar	93.5 ± 10.1		84.6 ± 6.1		78.1 ± 2.5		74.3 ± 1.9		63.8 ± 3.1	
LD-PE	96.9 ± 1.2		97.3 ± 1.0		95.8 ± 6.7		99.9 ± 1.9		99.2 ± 1.6

PBAT (w)	97.7 ± 0.9		99.3 ± 1.9		96.8 ± 1.6		96.6 ± 1.7		99.3 ± 1.9	

172 **3.2 POM size distribution**

173 None of the plastics shows a significant reduction of particle size due to ultrasonic treatment
174 within the 10 % and 50 % quantile. In contrast, at $\geq 100 \text{ J ml}^{-1}$ the particle size of farm and
175 forest oPOM was significantly reduced compared to the 0 J ml^{-1} treatment in both quantiles.
176 Ultrasonic treatment also causes a significant comminution of pyrochar, but of mainly the
177 smaller fraction indicated by the 10 % quantile, which appeared at $\geq 50 \text{ J ml}^{-1}$ and is only
178 interrupted due to an outlier at 100 J ml^{-1} . The 50 % quantile data (median) remain
179 insignificant. (Fig. 2a and 2b , Table 2)

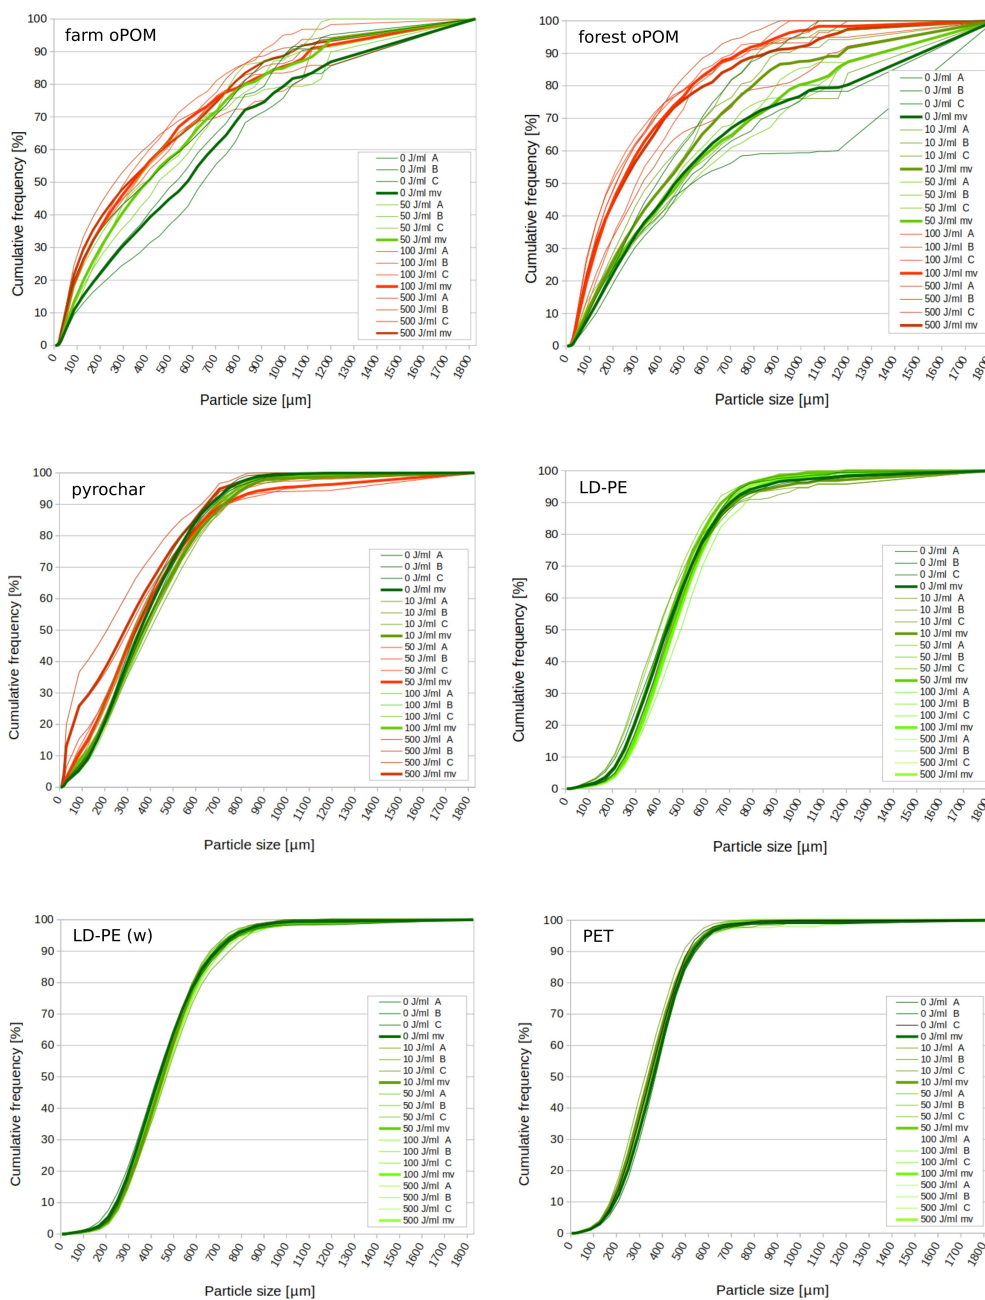

Figure 2a: Particle size distribution of natural POMs and microplastics after ultrasonic treatment with 0, 10, 50, 100 and 500 J ml⁻¹ (n=3). The (w) marks weathered plastics. Green graphs are similar to the 0 J ml⁻¹ treatment, red graphs significantly different by p<0.05 and comminution factor >1.1.

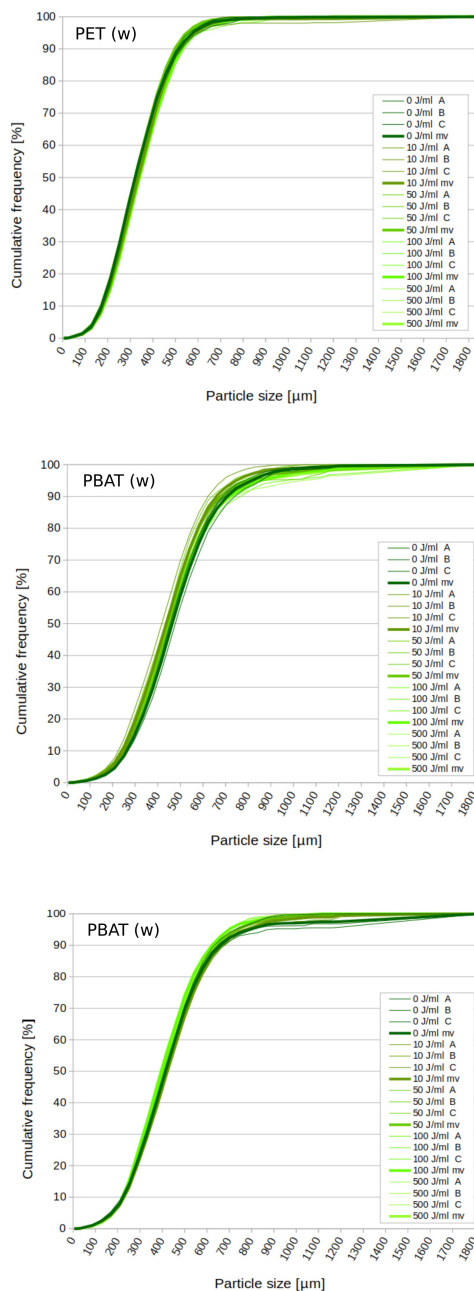

Figure 2b: Particle size distribution of microplastics after ultrasonic treatment with 0, 10, 50, 100 and 500 J ml⁻¹ (n=3). The (w) marks weathered plastics. Green graphs are similar to the 0 J ml⁻¹ treatment (p>0.05 or comminution factor ≤1.1).

Table 2: Particle size distribution (10 % and 50 % quantile) and comminution factor of natural POMs and microplastics after ultrasonic treatment with 0, 10, 50, 100 and 500 J ml⁻¹ (n=3). The (w) marks weathered plastics, mv mean value and sd standard deviation. Bold numbers are significantly different from the 0 J ml⁻¹ treatment by p<0.05 and comminution factor >1.1.

180 **4 Discussion**

181 Our experiments indicate that soil derived oPOM and pyrochar embedded into a fine sand
182 matrix are prone to comminution by ultrasonic treatment at energy levels of $\geq 50 \text{ J ml}^{-1}$. These
183 values are well below the 300 to 750 J ml^{-1} given in the literature for the complete
184 disaggregation of various soils (Amelung and Zech, 1999; Oorts et al., 2006; Yang et al.,
185 2009), namely in the range of values given for the destruction of macroaggregates (Amelung
186 and Zech, 1999; Kaiser and Berhe, 2014). In consequence, particle size reduction will appear
187 during most ultrasonic treatments aimed to extract oPOMs from soils. This underpins the
188 former implications by some authors that ultrasonic treatment could lead to particle size
189 artifacts. Microplastic, in contrast, shows a constant particle size distribution over all energy
190 levels and seems to resist ultrasonication within the tested range of 0 to 500 J ml^{-1} . The
191 recovery of microplastics also shows a constantly high rate of nearly 100 %, which is not
192 affected by the applied energy. In sharp contrast, the recovery rates of soil derived POMs and
193 pyrochar decreased with increasing energies from 95.0–78.6 % to 63.8–35.8 %, which
194 became significant at 50 to 100 J ml^{-1} and therefore is quite parallel to observed size
195 reduction.

196 The concurrent decrease of particle size and recovery rate of soil derived POMs and pyrochar
197 and their absence in microplastics indicate, that there is a causal relationship between
198 recovery rate and sensitivity against mechanical stress. We assume a mechanism that retains
199 particles at the mineral phase after comminution. Physical disruption of large and weak
200 particles increases the number of smaller ones, coming along with an increase of surface
201 area and, thus, surface forces (e.g. attraction through charges or hydrophobic interaction)
202 compared to volumetric forces (such as inertial forces). This causes an increased adsorption
203 of small POM to mineral surfaces immediately after the ultrasonic treatment and, in
204 consequence, a stronger retention of those particles observable as a lower recovery rate.
205 This effect appeared in our experiment from energies around 50 J ml^{-1} with the beginning
206 destruction of oPOM and might also occur with small-sized fPOM during density fractionation
207 without application of mechanical stress.

208 No matter if the hypothesis on the underlying mechanism is valid, as a consequence of
209 concurrent recovery rate and particle size reduction, farmland, forest and pyrochar POMs
210 remain within the soil sample the more they are disrupted by stronger ultrasonic treatment.
211 Thus, not only particle size artifacts are produced. With increasing energy level the extraction
212 of occluded POM is increasingly hindered and, thus, parts of small POM are extracted with
213 oPOM fractions at higher energy levels or remain within the heavy fraction – a carry-over
214 artifact. This leads to an overestimation of the more strongly bound POM fractions or the
215 mineral-associated organic matter (MOM), that natural part of the soil organic matter (SOM),
216 which is adsorbed on mineral surfaces of the heavy fraction and mainly assumed to be
217 molecular.

218 An overestimation would have an impact e.g. on the assessment of operationally defined
219 carbon pools within landscapes: POM is assigned to carbon pools with turnover times orders
220 of magnitude shorter than MOM, that endures hundreds of years. Misquantifications of these
221 pools, such as counting up to around 36.2 to 64.2 % of POM to the MOM as implied by this
222 work, would have phenomenal influence on e.g. the estimation of SOM decomposition and
223 CO₂ emissions from land-use change. Carrying-over SOM from little to highly decomposed
224 fractions also could alienate genuine C:N ratios, which strongly differ between the functional
225 carbon pools (Wagai et al., 2009).

226 Plastic, in turn, is not prone to disruption by ultrasonic treatment and its recovery rates are
227 stable in a wide range of energy levels. We therefore assume that there will be no carry-over
228 of particles due to comminution when extracting microplastics from soils with
229 ultrasonication/density fractionation. In consequence, the extractive performance is higher
230 and subsequent particle size measurements give more valid information about the original
231 particle size spectrum compared to the measurement of farmland, forest and pyrochar POM.
232 This is a positive sign for research on soil microplastic, however, it does not mean that
233 microplastic will be fully extracted from soils by this method. Soil microplastics appear within a
234 wide range of sizes between some nanometers and its upper limit of 5 mm by definition. Their
235 smallest part, produced by physical, chemical and biological erosion within the soil, might also
236 interact stronger with soil mineral surfaces than larger pieces causing enhanced retention
237 onto the soil matrix. Although we have introduced billions of tons of microplastics into
238 ecosystems since the 1950s (Thompson et al., 2009; Geyer et al., 2017), there are still
239 problems in producing microplastic fragments <100 µm on a laboratory scale with adequate
240 use of time and material to perform experiments within this size range.

241 **5 Conclusion**

242 Unlike weathered and fresh PE, PET and PBAT microplastic, soil derived POMs like occluded
243 POM from farm and forest soils and pyrochar concurrently show comminution and a reduced
244 recovery rate after ultrasonication and subsequent extraction from a sandy matrix. As
245 comminution increases the retention, parts of the farmland, forest and pyrochar POM remain
246 within fractions only extractable with higher energy levels or were bound to the heavy fraction,
247 so that they are misinterpreted as MOM. An overestimation as shown in this study might lead
248 to fundamentally different interpretations of physical protection of SOM, functional carbon
249 pools and the expected mineralization rates in consequence of e.g. land-use change. On the
250 contrary, the extraction of microplastics do not cause additional retention of particles at the
251 mineral phase and do not alienate the particle size spectrum by ultrasonic-driven
252 comminution. We conclude that density fractionation in combination with ultrasonication is an
253 appropriate tool for analyzing occlusion of microplastics within soil aggregates and studying
254 the size distribution of particulate microplastics.

255 **Author contribution**

256 Frederick Büks developed the experimental concept, extracted all samples and prepared the
257 manuscript. Gilles Kayser performed the particle size analysis. Antonia Zieger supported the
258 development of the experimental concept. Martin Kaupenjohann and Friederike Lang
259 supervised the whole study.

260 **Acknowledgement**

261 Many thanks to Zoltán Mátra, who kindly helped us to conduct the QICPIC analysis.

262 **Competing interests**

263 The authors declare that they have no conflict of interest.
