22

23 **Abstract**

24 Variations in precipitation and atmospheric N deposition affect water and N
25 availability in desert, and thus may have significant effects on desert ecosystems.
26 *Haloxylon ammodendron* is a dominant plant in Asian desert, and addressing its
27 physiological acclimatization to the changes in precipitation and N deposition can
28 provide an insight into how desert plants adapt extreme environment by physiological
29 adjustment. Carbon isotope ratio ($\delta^{13}\text{C}$) in plants has been suggested as a sensitive
30 long-term indicator of physiological acclimatization. Therefore, this study evaluated
31 the effect of precipitation change and increasing atmospheric N deposition on $\delta^{13}\text{C}$ of
32 *H. ammodendron*. Furthermore, *Haloxylon ammodendron* is a C_4 plant, whether its
33 $\delta^{13}\text{C}$ can indicate water use-efficiency (WUE) has not been addressed. In the present
34 study, we designed a field experiment with a completely randomized factorial
35 combination of N and water, and measured $\delta^{13}\text{C}$ and gas exchange of *H.*
36 *ammodendron*, then we calculated the degree of bundle-sheath leakiness (ϕ) and
37 WUE of the assimilating branches of *H. ammodendron*. $\delta^{13}\text{C}$ and ϕ remained stable
38 under N and water supply, while N addition, water addition and their interaction
39 affected gas exchange and WUE in *H. ammodendron*. In addition, $\delta^{13}\text{C}$ had no
40 correlation with WUE. These results were associated with the irrelevance between
41 $\delta^{13}\text{C}$ and the ratio of intercellular to ambient CO_2 concentration (c_i/c_a), which might
42 be caused by a special value (0.37) of the degree of bundle-sheath leakiness (ϕ) or a
43 lower activity of carbonic anhydrase (CA) of *H. ammodendron*. In conclusion, $\delta^{13}\text{C}$ of
44 *H. ammodendron* is not sensitive to global change in precipitation and atmospheric N

45 deposition, and cannot be used for indicating its WUE.

46

47 **1 Introduction**

48 Recently, global precipitation pattern has changed significantly (Frank et al., 2015;
49 Knapp et al., 2015), and atmospheric N deposition has continued to rise (Galloway et
50 al., 2004; Liu et al., 2013; Song et al., 2017). Previous researchers have suggested that
51 arid ecosystems are most sensitive to climate change (Reynolds et al., 2007; Huang et
52 al., 2016), while global change in precipitation and atmospheric N deposition has an
53 important impact on water and N availability in desert (Huang et al., 2018). Thus,
54 these changes may have significant effects on desert ecosystems. *Haloxylon*
55 *ammodendron* is a dominant species in desert regions, especially in Asia. Studying the
56 physiological responses of *H. ammodendron* to global change can provide an insight
57 into how desert plants adapt extreme environment by physiological adjustment.
58 Carbon isotope ratio ($\delta^{13}\text{C}$) in plants depends on the ratio of intercellular to ambient
59 CO_2 concentration (c_i/c_a), which reflects the balance between inward CO_2 diffusion
60 rate, regulated by stomatal conductance (g_s), and CO_2 assimilating rate (A) (Farquhar
61 and Richards, 1984), and has been suggested as a sensitive long-term indicator of
62 physiological acclimatization (Battipaglia et al., 2013; Cernusak et al., 2013; Tranan
63 and Schubertt, 2016; Wang and Feng, 2012). Therefore, investigating the variations in
64 $\delta^{13}\text{C}$ of *H. ammodendron* under water and nitrogen addition can enhance
65 understanding of physiological responses of desert plants to future changes in
66 precipitation and atmospheric N deposition.

67 A large quantity of works has been devoted to the relationships between C₃ plant
68 $\delta^{13}\text{C}$ and water availability or precipitation (e.g., Diefendorf et al., 2010; Kohn, 2010;
69 Liu et al., 2005; Ma et al., 2012; Serret et al., 2018; Stewart et al., 1995; Wang et al.,
70 2005, 2008) and nitrogen availability (e.g. Cernusak et al., 2007; Li et al., 2016;
71 Sparks and Ehleringer, 1997; Yao et al., 2011; Zhang et al., 2015). However, a
72 relatively small amount of research has focused on the responses of C₄ plant $\delta^{13}\text{C}$ to
73 water availability or precipitation (Ellsworth et al., 2017; Liu et al., 2005; Rao et al.,
74 2017; Wang et al., 2006) and nitrogen availability (Ma et al., 2016; Schmidt et al.,
75 1993). For C₄ plants, $\delta^{13}\text{C}$ is controlled by both the c_i/c_a ratio and the degree of
76 bundle-sheath leakiness (ϕ), the proportion of CO₂ produced within bundle sheath
77 cells from C₄ acids that leaks back to mesophyll cells (Ellsworth and Cousins, 2016;
78 Ellsworth et al., 2017; Farquhar, 1983). Thus, the responses of C₄ plant $\delta^{13}\text{C}$ to water
79 and N availability are also affected by ϕ . Genetic factors control ϕ values, which
80 causes the interspecific differences in $\delta^{13}\text{C}$, even the responses of plant $\delta^{13}\text{C}$ to water
81 and N availability (Gresset et al., 2014). On the other hand, enzymatic activity of
82 carbonic anhydrase (CA) may influence $\delta^{13}\text{C}$ in C₄ plants (Cousins et al., 2006). CA is
83 an enzyme that catalyzes the hydration of CO₂ in mesophyll cells to form bicarbonate
84 (HCO_3^-). Previous studies showed that CA activity in most C₄ plants is usually low,
85 just sufficient to support photosynthesis (Cousins et al., 2006; Gillon and Yakir, 2000,
86 2001; Hatch and Burnell, 1990). *H. ammodendron* is a typical C₄ plant. How its $\delta^{13}\text{C}$
87 responds to water and N availability has never been addressed.

88 Foliar $\delta^{13}\text{C}$ in C₃ plants has been considered as a useful indicator of intrinsic water

89 use-efficiency (WUE) (Farquhar, 1983). However, although some studies have
90 suggested that $\delta^{13}\text{C}$ of C_4 plants could also indicate its WUE (Henderson et al., 1992;
91 Wang et al., 2005; Cernusak et al., 2013; Ellsworth and Cousins, 2016), this statement
92 is still controversial. The relationship between $\delta^{13}\text{C}$ and WUE is based on the links
93 between c_i/c_a ratio and $\delta^{13}\text{C}$ and between c_i/c_a ratio and WUE (Ehleringer and Cerling,
94 1995). For C_3 plants, $\delta^{13}\text{C}$ always decreases with an increase in c_i/c_a ratio; but for C_4
95 plants, the correlation between $\delta^{13}\text{C}$ and c_i/c_a ratio depends on ϕ value (Cernusak et al.,
96 2013) and CA activity (Cousins et al., 2006). As mentioned above, ϕ value is under
97 genetic control, and the CA activity changes across species (Cousins et al., 2006;
98 Gillon and Yakir, 2000, 2001; Hatch and Burnell, 1990), thus, the correlation between
99 $\delta^{13}\text{C}$ and c_i/c_a ratio, as well as the relationship between WUE and $\delta^{13}\text{C}$, shows
100 interspecific difference. Whether $\delta^{13}\text{C}$ of *H. ammodendron* indicates WUE has never
101 been evaluated.

102 In this study, we designed an experiment with multiple water and nitrogen supply in
103 the southern Gurbantunggut Desert in Xinjiang Uygur Autonomous Region, China.
104 We measured the $\delta^{13}\text{C}$, gas exchange and WUE of the assimilating branches of *H.*
105 *ammodendron*. We had two objectives. One objective was to evaluate the response of
106 the dominant plant of Asian desert to future changes in precipitation and atmospheric
107 N deposition by revealing the effects of water and N supply on $\delta^{13}\text{C}$ of *H.*
108 *ammodendron*. The other was to explore the availability of $\delta^{13}\text{C}$ as the indicator of
109 water use-efficiency in *H. ammodendron*.

110

111 2 Materials and methods

112 2.1 Definitions and Basic Equations

113 Stable carbon isotopic ratio ($\delta^{13}\text{C}$) of natural materials is expressed as:

$$114 \quad \delta^{13}\text{C}(\text{‰}) = \left[\frac{(^{13}\text{C}/^{12}\text{C})_{\text{sample}}}{(^{13}\text{C}/^{12}\text{C})_{\text{standard}}} - 1 \right] \times 1000 \quad (1)$$

115 where $(^{13}\text{C}/^{12}\text{C})_{\text{sample}}$ and $(^{13}\text{C}/^{12}\text{C})_{\text{standard}}$ are the $^{13}\text{C}/^{12}\text{C}$ ratio of the sample and of Pee
116 ~~Dee Belemnite standard (PDB), respectively. the standard is the carbon dioxide~~
117 ~~obtained from the Peedee belemnite (PDB) limestone (Craig, 1957).~~ Farquhar (1983)

118 proposed the pattern of carbon isotopic discrimination (Δ) in C_4 plant:

$$119 \quad \Delta = \frac{\delta^{13}\text{C}_{\text{air}} - \delta^{13}\text{C}_{\text{plant}}}{1 + \delta^{13}\text{C}_{\text{plant}}/1000} \approx \delta^{13}\text{C}_{\text{air}} - \delta^{13}\text{C}_{\text{plant}} = a + [b_4 + \varphi (b - s) - a] \frac{c_i}{c_a} \quad (2)$$

120 where $\delta^{13}\text{C}_{\text{plant}}$ and $\delta^{13}\text{C}_{\text{air}}$ are the $\delta^{13}\text{C}$ values of plants and CO_2 in the ambient air,
121 respectively. The parameter a ($= 4.4\text{‰}$, Craig, 1954) is the carbon isotopic
122 fractionation in the diffusion of CO_2 into internal leaves; b_4 ($= -5.9\text{‰}$, O'Leary, 1984)
123 is the combined carbon isotopic fractionations occurring in the processes of gaseous
124 CO_2 dissolution, hydration/dehydration reactions of CO_2 and HCO_3^- in mesophyll
125 cells, and HCO_3^- carboxylation by PEP (phosphoenolpyruvate) carboxylase; s ($= 1.8\text{‰}$,
126 O'Leary, 1984) is the carbon isotopic fractionation during diffusion of CO_2 out of the
127 bundle-sheath cells, and b ($= 27\text{‰}$, Farquhar and Richards, 1984) is the carbon
128 isotopic fractionation of CO_2 carboxylation by RuBP (ribulose-1,5-bisphosphate)
129 carboxylase. The variable φ is the proportion of CO_2 producing within bundle sheath
130 cells from C_4 acids that leaks back to mesophyll cells, and c_i/c_a is the ratio of
131 intercellular to ambient CO_2 concentration. Eq. (2) can be transformed into the
132 following format:

133
$$\delta^{13}\text{C}_{\text{plant}} = -[b_4 + \varphi(b - s) - a] \frac{c_i}{c_a} + \delta^{13}\text{C}_{\text{air}} - a \quad (3)$$

134 According to Eq. (3), if the coefficient $[b_4 + \varphi(b - s) - a]$ is greater than 0, $\delta^{13}\text{C}$
 135 decreases with increasing c_i/c_a ; if this coefficient is lower than 0, $\delta^{13}\text{C}$ increases with
 136 increasing c_i/c_a .

137 Water use-efficiency (WUE) is defined as the amount of assimilated carbon dioxide
 138 by plants under the consumption of per unit water. There are two characteristics of
 139 WUE, instantaneous WUE (ins-WUE) and intrinsic WUE (int-WUE), respectively.
 140 ins-WUE can be calculated by:

141
$$\text{ins-WUE} = A/E = (c_a - c_i)/1.6v = c_a(1 - c_i/c_a)/1.6v \quad (34)$$

142 where A is photosynthetic rate, E is transpiration rate and v is calculated
 143 by:

144
$$v = (e_i - e_a)/p \quad (45)$$

145 where e_i and e_a are the water vapor pressure inside and outside the leaves, p is the
 146 atmospheric pressure.

147 The definition of int-WUE is:

148
$$\text{int-WUE} = A/g_s = (c_a - c_i)/1.6 = c_a(1 - c_i/c_a)/1.6 \quad (56)$$

149 where g_s is stomatal conductance.

150 **2.2 Study site and species**

151 This experiment was conducted at the Fukang Station of Desert Ecology, Chinese
 152 Academy of Sciences, on the southern edge of the Gurbantunggut Desert (44°26' N,
 153 87°54' E) in northwestern China. The altitude of the study site is 436.8 m above
 154 average sea level (a.s.l.). It is a typical continental arid, temperate climate, with a hot

155 summer and cold winter in the area. The mean annual temperature is 7.1°C and the
156 mean annual precipitation is 215.6 mm, with a potential evaporation of about 2000
157 mm. The mean annual temperature and the annual rainfall amount in the sampling
158 year are 10.23°C and 122.7 mm (Cui, 2018). The soil type is grey desert soils
159 (Chinese classification) with aeolian sands on the surface (0-100 cm). The
160 percentages of clay (< 0.005 mm), silt (0.005-0.063 mm), fine sand (0.063-0.25 mm)
161 and medium sand (0.25-0.5 mm) range from 1.63-1.76%, 13.79-14.15%,
162 55.91-56.21% and 20.65-23.23%, respectively (Chen et al., 2007). The soil is highly
163 alkaline (pH = 9.55 ± 0.14) with low fertility. The vegetation is dominated by
164 *Haloxylon ammodendron* and *Haloxylon persicum* with about 30% coverage. Herbs
165 include ephemerals, annuals and small perennials, with a cover of ca. 40% (Fan et al.,
166 2013). Although the coverage of the two *Haloxylon* species is a little lower than that
167 of herbs, the biomass of the former is much larger than that of the latter, because
168 *Haloxylon* plants are shrubs with an average height of 1.5 m whereas the latter are
169 very low herbaceous plants. Biological soil crusts are distributed widely on the soil
170 between the herbs and *Haloxylon*, with almost 40% coverage (Zhang et al., 2007).

171 The present study focused on *Haloxylon ammodendron* because it is the dominant
172 species in Asian desert. *Haloxylon ammodendron* is a species of Chenopodiaceae,
173 which is a xerophytic and halophytic woody plant (Cui et al., 2017). The leaves of *H.*
174 *ammodendron* have been completely degraded due to the extreme drought, and the
175 assimilation branches, which are the glossy green branches (Fig. S1), perform the
176 same functions as the leaves. Due to its drought tolerance, *H. ammodendron* is widely

177 distributed in desert areas.

178 **2.3 Experimental design**

179 A field experiment with a completely randomized factorial combination of water and
180 nitrogen has been conducted from 2014 to 2017. We designed two water addition
181 levels (0, 60mm·yr⁻¹; W0, W1) based on the prediction that precipitation will increase
182 by 30% in northern China in the next 30 years (Liu et al., 2010), and three levels of N
183 addition (0, 30, 60 kg N·ha⁻¹·yr⁻¹; N0, N1 and N2), because N deposition has reached
184 35.4 kg N·ha⁻¹·yr⁻¹ in the nearby city, Urumqi (Cui et al., 2017) and will double by
185 2050 relative to the early 1990s (Galloway et al., 2008). Therefore, there were six
186 treatments (W0N0, W0N1, W0N2, W1N0, W1N1, W1N2) in this experiment. Four
187 replicates of each treatment were set, making a total of 24 plots with a size of 10 m
188 × 10 m. A small sub-plot with a size of 1.5 m×1.5 m was set in each plot. A
189 well-grown *H. ammodendron* was enclosed in the center of the sub-plot. The average
190 height and coverage of an individual *H. ammodendron* were 1.5 m and 1.9 m²,
191 respectively, and did not vary significantly across the plots. The type of nitrogen used
192 in the present study is NH₄NO₃. To simulate natural water and N inputs, the
193 treatments were applied in equal amounts, twelve times, once a week in April, July
194 and September, as 5 mm·m⁻² of water and 2.5 or 5 kg N·ha⁻¹ each week (Cui et al.,
195 2017). Usually, water addition was with a sprinkler kettle, irrigating over the canopy
196 of *H. ammodendron*.

197 **2.4 Measurements of gas exchange and WUE**

198 ~~The leaves of *H. ammodendron* have been completely degraded due to the extreme~~

199 ~~drought, and~~ As mentioned above, the main assimilating organ of *H. ammodendron* is
200 the assimilation branches ~~perform the same functions as the leaves~~. Thus, we
201 conducted gas exchange measurements on the assimilation branches of the *H.*
202 *ammodendron* grown in the sub-plots by LI-6400 portable photosynthesis system. The
203 measurements were conducted on 27-29, June 2016, which is the main growing
204 season of *H. ammodendron*. It may be the most appropriate to take measurements
205 during this period, and the results of the measurements are therefore more
206 representative. Previous studies have also usually conducted this measurement during
207 the growing season (Nyongesah and Wang, 2013; Cui, 2018; Gong et al., 2019). The
208 ins-WUE and the int-WUE were calculated based on these measured gas exchange
209 traits by the Eq. (34), and int-WUE by Eq. (56). At each plot, the top assimilating
210 branches of a mature individual was selected randomly for the measurement of gas
211 exchange, which includes photosynthetic rate (A), stomatal conductance (g_s),
212 transpiration rate (E), the ambient CO_2 concentration (c_a) and the intercellular CO_2
213 concentration (c_i). ~~About~~ Before the measurement of gas exchange, it takes about 5s
214 to stabilize ~~—was needed for stability~~ after the assimilating branches was inserted in
215 the cuvette ~~and then the assimilating branches were measured~~. We repeated 10 times
216 on the same assimilating branches for each measurement. Our measurements were
217 carried out under the conditions of ~~We measured gas exchange with~~ a standard 450
218 $mmol \cdot mol^{-1}$ CO_2 concentration at a flow rate of $500 \text{ mmol} \cdot s^{-1}$ above saturation in
219 photo flux density of $1600 \text{ mmol} \cdot m^{-2} \cdot s^{-1}$. The temperature of the measuring
220 assimilating branches varied from $29.5 \text{ }^\circ\text{C}$ to $30.5 \text{ }^\circ\text{C}$ during the entire period of gas

221 exchange measurements.

222 **2.5 Samples collection**

223 Sample collection was conducted in 20, July, during the addition of water and
224 nitrogen. Considering that there is a considerable difference in $\delta^{13}\text{C}$ between buds,
225 young and matured leaves, so we collected the mature assimilating branches of *H.*
226 *ammodendron* for the $\delta^{13}\text{C}$ measurements. All *H. ammodendron* individuals grown in
227 plots (10 m \times 10 m) were sampled. Eight pieces of the mature assimilating branches
228 (15-20 cm long) were collected from each individual; two pieces of assimilating
229 branches were collected at each of the four cardinal directions from the positions of
230 full irradiance. All assimilating branches from the same plot were combined into one
231 sample. After the samples were collected, they were immediately divided into two
232 parts randomly and taken back to the laboratory at Fukang Station. The first part was
233 used to determine the chlorophyll content. The second part was immediately
234 inactivated in a 105 °C oven in the laboratory at Fukang Station, and then brought
235 back to Beijing in a ziplock bag. The time interval between sample collection and
236 inactivation is very short. After inactivation, the carbon exchange of the assimilating
237 branches stop, so the isotope composition of the samples will not change anymore.
238 All plant samples of the second part were air-dried ~~immediately in the field and then~~ in
239 the laboratory in Beijing. Then the samples were ground into a fine powder using a
240 steel ball mixer mill MM200 (Retsch GmbH, Haan, Germany) for the measurements
241 of $\delta^{13}\text{C}$, and N contents ~~and chlorophyll contents~~.

242 **2.6 Measurements of plant $\delta^{13}\text{C}$, plant N and chlorophyll contents**

243 The $\delta^{13}\text{C}$ and N measurements were performed on a Delta^{Plus} XP mass spectrometer
 244 (Thermo Scientific, Bremen, Germany) coupled with an automated elemental
 245 analyzer (Flash EA1112, CE Instruments, Wigan, UK) in a continuous flow mode, at
 246 the Stable Isotope Laboratory of the College of Resources and Environmental
 247 Sciences, China Agricultural University. The carbon isotopic ratios were reported in
 248 the delta notation relative to the V-PDB standard. For this measurement, we obtained
 249 standard deviations low than 0.15‰ for $\delta^{13}\text{C}$ among replicate measurements of the
 250 same sample. And standard deviations for the N measurements were 0.1%.

251 The chlorophyll contents of all samples were ~~also~~ determined immediately when
 252 the sample were taken back in the laboratory at Fukang Station. The samples were
 253 first extracted by 95% ethyl alcohol (0.5 g sample to 25 mL ethyl alcohol), and then
 254 the absorbancy was measured under the wave length of 665 and 649 nm by the
 255 spectrophotometer. The content of chlorophyll a, b was calculated by the follow
 256 equations:

$$257 \quad \text{Chlorophyll a (mg/L)} = 13.95 \times \text{OD}_{665} - 6.88 \times \text{OD}_{649} \quad (67)$$

$$258 \quad \text{Chlorophyll b (mg/L)} = 24.96 \times \text{OD}_{649} - 7.32 \times \text{OD}_{665} \quad (78)$$

259 where OD₆₆₅ and OD₆₄₉ are the absorbancy under the wave length of 665 and
 260 649nm, respectively.

261 **2.6.7** Calculation of the degree of bundle-sheath leakiness

262 The degree of bundle-sheath leakiness (ϕ) was calculated by the transformation of Eq.

263 (2):

$$264 \quad \phi = \left(\frac{(\delta^{13}\text{C}_{\text{air}} - \delta^{13}\text{C}_{\text{plant}}) / (1 + \delta^{13}\text{C}_{\text{plant}}/1000) - a}{c_i/c_a} + a - b_4 \right) / (b - s) \quad (89)$$

265 In this equation, parameters a , b_4 , b and s are constant, while $\delta^{13}\text{C}_{\text{plant}}$ and c_i/c_a are
266 the measured values of our samples. We did not measure the $\delta^{13}\text{C}_{\text{air}}$ at our study site,
267 so we had to use an approximation of the $\delta^{13}\text{C}_{\text{air}}$ to do this ϕ calculation. The
268 approximated value we used is -9.77‰ , which has been measured at Donglingshan
269 Mountain, Beijing, north China in September 2019. The two sites should have similar
270 $\delta^{13}\text{C}_{\text{air}}$ because the two sites are located in countryside with less human activities and
271 have a similar distance from the nearest city. The straight line distances between
272 Donglingshan Mountain and the city center of Beijing, and between our study site and
273 Urumqi city are about 90 km. In addition, since the $\delta^{13}\text{C}_{\text{air}}$ has large diurnal and
274 seasonal variations, we used the published range of $\delta^{13}\text{C}_{\text{air}}$ from May to July in
275 Shangdianzi, China (Data comes from Global Monitoring Laboratory, Earth System
276 Research Laboratories, <https://www.esrl.noaa.gov/gmd>) to calculate the minimum and
277 maximum $\delta^{13}\text{C}_{\text{air}}$ of the time period, which is the main growing season for *H.*
278 *ammოდendron*. Finally, the $\delta^{13}\text{C}_{\text{air}}$ used in the calculation ranged from -10.52‰ to
279 -9.01‰ with an average of -9.77‰ .

280 **2.87 Statistical analysis**

281 Statistical analyses were conducted using SPSS software (SPSS for Windows, Version
282 20.0, Chicago, IL, United States). One-way analysis of variance (ANOVA) and
283 two-way analysis of variance (ANOVA) were used to compare the difference of $\delta^{13}\text{C}$
284 and other physiological traits between each treatment. Pearson analysis was used to
285 determine the correlation among $\delta^{13}\text{C}$, WUE and c_i/c_a in *H. ammოდendron*.

286

287 **3 Results**

288 **3.1 Plant $\delta^{13}\text{C}$ under water and nitrogen addition**

289 The $\delta^{13}\text{C}$ of the assimilating branches of *H. ammodendron* in the six treatments
290 W0N0, W0N1, W0N2, W1N0, W1N1, W1N2 was $-14.18 \pm 0.19 \text{ ‰}$, $-14.71 \pm 0.35 \text{ ‰}$,
291 $-14.45 \pm 0.18 \text{ ‰}$, $-14.67 \pm 0.40 \text{ ‰}$, $-14.65 \pm 0.38 \text{ ‰}$, $-14.34 \pm 0.29 \text{ ‰}$, respectively.
292 One-way ANOVA analyses showed no significant variation in $\delta^{13}\text{C}$ across treatments
293 ($p = 0.79$, Fig. 1). Two-way ANOVA analyses suggested that $\delta^{13}\text{C}$ was not affected by
294 water addition ($p = 0.68$), N addition ($p = 0.61$) and their interaction ($p = 0.56$, Table
295 1).

296 Fig.1

297 Table 1

298 **3.2 Gas exchange and WUE under water and nitrogen addition**

299 Photosynthetic rate (A), stomatal conductance (g_s), transpiration rate (E) and c_i/c_a
300 ranged from $12.11 \mu\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$ to $39.35 \mu\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$, from $0.09 \text{ mol H}_2\text{O}$
301 $\text{m}^{-2} \text{ s}^{-1}$ to $0.31 \text{ mol H}_2\text{O m}^{-2} \text{ s}^{-1}$, from $2.87 \text{ mmol H}_2\text{O m}^{-2} \text{ s}^{-1}$ to $8.49 \text{ mmol H}_2\text{O m}^{-2} \text{ s}^{-1}$
302 and 0.11 to 0.57 , respectively. One-way ANOVA analyses showed significant changes
303 in leaf gas exchange across the six treatments ($p = 0.01$ for A , $p < 0.01$ for g_s , $p < 0.01$
304 for E and c_i/c_a , Fig. 2). Two-way ANOVA analyses suggested that water addition
305 had exerted effect on c_i/c_a ($p < 0.01$), that N additions influenced A ($p < 0.01$) and c_i/c_a
306 ($p = 0.009$), and that the interaction between water and N supply played a role in g_s (p
307 < 0.001), E ($p < 0.001$) and c_i/c_a ($p < 0.001$, Table 1).

308 Fig. 2

309 Instantaneous WUE (ins-WUE) and intrinsic WUE (int-WUE) ranged from 3.09
310 $\mu\text{mol CO}_2 / \text{mmol H}_2\text{O}$ to $8.49\mu\text{mol CO}_2 / \text{mmol H}_2\text{O}$ and from $93.64\mu\text{mol CO}_2 / \text{mol}$
311 H_2O to $208.47\mu\text{mol CO}_2 / \text{mmol H}_2\text{O}$, respectively. One-way ANOVA analyses
312 showed significant changes in these two indexes across these treatments (both $p <$
313 0.001 , Fig. 3). Two-way ANOVA analyses suggested that water addition, N addition
314 and their interaction all have significant effect on these two indexes (all $p < 0.05$,
315 Table 1).

316 Fig. 3

317 **3.3 Correlations among $\delta^{13}\text{C}$, WUE and c_i/c_a ratio**

318 In order to test whether $\delta^{13}\text{C}$ in *H. ammodendron* can indicate WUE, the relationships
319 among $\delta^{13}\text{C}$, ins-WUE, int-WUE and c_i/c_a ratio were revealed in this study. Our
320 results showed no correlation between $\delta^{13}\text{C}$ and ins-WUE ($p = 0.23$, Fig. 4a), between
321 $\delta^{13}\text{C}$ and int-WUE ($p = 0.23$, Fig. 4c), and between $\delta^{13}\text{C}$ and c_i/c_a ratio ($p = 0.18$, Fig.
322 4e). However, there was a negative correlation between ins-WUE and c_i/c_a ratio ($p <$
323 0.001 , Fig. 4b), and between int-WUE and c_i/c_a ratio ($p < 0.001$, Fig. 4d).

324 Fig. 4

325 **3.4 The degree of bundle-sheath leakiness under water and nitrogen addition**

326 ~~The calculated~~ ϕ value calculated from the minimum $\delta^{13}\text{C}_{\text{air}}$ ranged from 0.16 to
327 0.50 with a mean value of 0.35; the ϕ value calculated from the maximum $\delta^{13}\text{C}_{\text{air}}$
328 ranged from 0.44 to 0.70 with a mean value of 0.55, and the ϕ value calculated from
329 the average $\delta^{13}\text{C}_{\text{air}}$ ranged from 0.32 to 0.59 with a mean value of 0.45. One-way
330 ANOVA analyses showed no significant variation in ϕ calculated from the minimum,

331 average and maximum $\delta^{13}\text{C}_{\text{air}}$ across treatments (p = 0.60 for the ϕ calculated from the
332 minimum $\delta^{13}\text{C}_{\text{air}}$, p = 0.77 for the ϕ calculated from the average $\delta^{13}\text{C}_{\text{air}}$, and p = 0.90
333 for the ϕ calculated from the maximum $\delta^{13}\text{C}_{\text{air}}$, Fig. 5). Two-way ANOVA analyses
334 suggested that ϕ was not affected by water addition (p = 0.46 for the ϕ calculated
335 from the minimum $\delta^{13}\text{C}_{\text{air}}$, p = 0.64 for the ϕ calculated from the average $\delta^{13}\text{C}_{\text{air}}$, and
336 p = 0.98 for the ϕ calculated from the maximum $\delta^{13}\text{C}_{\text{air}}$), N addition (p = 0.65 for the
337 ϕ calculated from the minimum $\delta^{13}\text{C}_{\text{air}}$, p = 0.60 for the ϕ calculated from the average
338 $\delta^{13}\text{C}_{\text{air}}$, and p = 0.55 for the ϕ calculated from the maximum $\delta^{13}\text{C}_{\text{air}}$) and their
339 interaction (p = 0.30 for the ϕ calculated from the minimum $\delta^{13}\text{C}_{\text{air}}$, p = 0.52 for the ϕ
340 calculated from the average $\delta^{13}\text{C}_{\text{air}}$, and p = 0.87 for the ϕ calculated from the
341 maximum $\delta^{13}\text{C}_{\text{air}}$, p = 0.52), Table 1).

342 Fig. 5

343

344 **4 Discussion**

345 The $\delta^{13}\text{C}$ of the assimilating branches in *H. ammodendron* did not change across
346 treatments (Fig. 1, Table 1), suggesting that neither water addition nor nitrogen
347 addition influenced the $\delta^{13}\text{C}$ of *H. ammodendron*. Previous studies also reported no
348 significant relationship between $\delta^{13}\text{C}$ of C_4 plant and water availability (Swap et al.,
349 2004; Wang et al., 2008), and between $\delta^{13}\text{C}$ of C_4 plant and nitrogen availability (Yao
350 et al., 2011, Yang et al., 2017).

351 In general, the effects of water availability and nitrogen availability on $\delta^{13}\text{C}$ are
352 dependent on c_i/c_a ratio, which reflects the balance between stomatal conductance (g_s)

353 and photosynthetic rate (A) (Farquhar and Richards, 1984). Stomatal conductance (g_s)
354 usually increases ~~W~~with more-increasing water availability under water addition,
355 ~~plants tend to open stomata to absorb more CO_2 , leading to an increase in g_s .~~ Although
356 two-way ANOVA analyses suggested that water addition had no effect on both A and
357 g_s (Table 1); one-way ANOVA analyses showed that g_s was higher in W1N0 than that
358 in W0N0 (Fig. 2b), indicating that water addition had a positive effect on g_s under
359 ambient N condition. Increasing g_s under water supply will lead to the rise of
360 intercellular CO_2 because of the decrease of diffusional resistance to CO_2 . As the
361 results, c_i/c_a ratio was observed to increase with increasing moisture (Fig. 2d, Table 1).
362 However, $\delta^{13}C$ remained stable under water addition (Fig. 1, Table 1). Thus, c_i/c_a ratio
363 could not explain the observed response of $\delta^{13}C$ to water supply.

364 For most plants in natural ecosystems, nitrogen is the key factor limiting plant
365 growth (Hall et al., 2011). Thus, nitrogen addition usually causes plants to absorb
366 more N. However, extreme drought could prevent plants from absorbing N even
367 under high N supply. In the present experiment, N supply was found to have an effect
368 on N contents in *H. ammodendron*. Relative to the control treatment (W0N0), N
369 contents increased with N supply under low N addition, but kept unchanged under
370 high addition (Table S1, S2). Nitrogen is the main constituent of Rubisco (ribulose -
371 1,5 - biphosphate carboxylase oxygenase) and chlorophyll in plants. Thus,
372 chlorophyll a was found to have the similar pattern as N contents under water and N
373 supply. Chlorophyll a was higher in W0N1 than W0N0, and there was no difference in
374 chlorophyll a between W0N0 and W0N2 (Table S1). Increasing chlorophyll contents

375 in W0N1 should lead to the increase in photosynthetic rate (A). However, different
376 from our prediction, one-way ANOVA analyses suggested that A in W0N1 did not
377 differ from that in W0N0, and that A in W0N2 was lower than that in W0N0 (Fig., 2a).
378 Two-way ANOVA analyses showed that N addition had an influence on A (Table 1).
379 Both the analyses suggested that N supply played a negative role in A. These results
380 might be associated with the extremely high light intensity at the study site. Due to the
381 high light intensity, photosynthetic rate might not be correlated with chlorophyll
382 contents (Gabrielsen, 1948). The negative effect of N supply on A led to the decrease
383 in and thus the consumption of intercellular CO₂. Consequently, c_i/c_a ratio increased
384 with N supply (Fig. 2d, Table 1). Therefore, the variations in c_i/c_a ratio with N
385 addition could not account for the unchanged pattern in δ¹³C under N supply (Fig. 1).

386 The co-application of water and nitrogen had a negative effect on A but no effect on
387 g_s (W0N0 vs. W1N1, W1N2, Fig. 2a, b). The responses of A and g_s to the
388 co-application of water and nitrogen resulted in an increase in c_i/c_a ratio (Fig., 2d).
389 Since δ¹³C remained unchanged under the co-application of water and nitrogen (Fig.
390 1), c_i/c_a ratio could not also explain the observed δ¹³C response to the co-application
391 of water and nitrogen.

392 In summary, the unchanged δ¹³C across treatments was not dependent on the c_i/c_a
393 ratio in *H. ammodendron* (Fig. 4e). The observed δ¹³C stability across treatments
394 might be associated with the φ value and carbonic anhydrase (CA) in *H.*
395 *ammodendron*. For C₄ plants, the relationship between carbon isotope discrimination
396 ($\Delta \approx \delta^{13}\text{C}_{\text{air}} - \delta^{13}\text{C}_{\text{plant}}$, see Eq. (2)) and c_i/c_a ratio is controlled by φ values (Ellsworth

397 and Cousins, 2016; Ellsworth et al., 2017; Farquhar, 1983; Wang et al., 2008). Some
398 studies suggested that ϕ value was stable for a given species under a wide range of
399 environmental conditions (Henderson et al., 1992; Wang et al., 2008; Cernusak et al.,
400 2013). However, other studies had different conclusions that ϕ value was influenced
401 by irradiation (Bellasio and Griffiths, 2014; Kromdijk et al., 2010; Pengelly et al.,
402 2010; Ubierna et al., 2013), temperature (von Caemmerer et al., 2014), water stress
403 (Fravolini et al., 2002; Gong et al., 2017; Williams et al., 2001; Yang et al., 2017) and
404 nitrogen supply (Fravolini et al., 2002; Meinzer and Zhu, 1998; Yang et al., 2017). In
405 current study, the ϕ value of *H. ammodendron* remained unchanged across six
406 treatments (Fig. 5), and two-way ANOVA analyses suggested that water supply and N
407 supply had no effect on ϕ (Table 1). Therefore, the ϕ value of *H. ammodendron* was
408 insensitive to water and N addition in this study. Even if the ϕ value remains stable,
409 the relationship between Δ and c_i/c_a ratio is also associated with the magnitude of the
410 ϕ value. Cernusak et al. (2013) predicted that when ϕ value is greater than 0.37, the
411 correlation between Δ and c_i/c_a ratio is positive; conversely, when ϕ value is less than
412 0.37, the correlation is negative. In particular, when ϕ value is equal to 0.37, there will
413 be no correlation between them, because the coefficient ($[b_4 + \phi (b - s) - a]$ in Eq. (2))
414 of c_i/c_a ratio equals to 0 (Cernusak et al., 2013). The ϕ value calculated from the
415 average $\delta^{13}C_{air}$ ranged from 0.32 to 0.59 with a mean value of 0.45 in present study.
416 Thus, the correlation between Δ and c_i/c_a in *H. ammodendron* should be positive
417 based on the prediction by Cernusak et al. (2013). Δ always changes in the opposite
418 direction to $\delta^{13}C_{plant}$ changes according to Eq. (2), thus, a negative relationship

419 between $\delta^{13}\text{C}_{\text{plant}}$ and c_i/c_a is expected. In fact, this study observed no correlation
420 between $\delta^{13}\text{C}$ and c_i/c_a in *H. ammodendron* (Fig. 4e); this indicates that ϕ was not the
421 driver of the observed $\delta^{13}\text{C}$ pattern in *H. ammodendron*. However, the measured $\delta^{13}\text{C}$
422 represents the fixed carbon isotope composition throughout the assimilation branch
423 formation period, which usually spans at least several weeks. And the measured c_i/c_a
424 is an instant indicator. As a result, there were some uncertainties in the calculation of
425 ϕ value using Eq. (2) based on the measured $\delta^{13}\text{C}$ and c_i/c_a . ~~The measured $\delta^{13}\text{C}$~~
426 ~~represents the fixed carbon isotope composition throughout the assimilation branch~~
427 ~~formation period, which usually spans at least several weeks. And the measured c_i/c_a~~
428 ~~is a instant indicator.~~ In addition, the mean ϕ value calculated from the minimum and
429 maximum $\delta^{13}\text{C}_{\text{air}}$ were 0.35 and 0.55, respectively. Therefore, suggesting that the ϕ
430 value of *H. ammodendron* might be close to 0.37, which led to the observed
431 insensitive response of $\delta^{13}\text{C}$ to water and N addition.

432 The enzymatic activity of CA may be another mechanism behind the unchanged
433 $\delta^{13}\text{C}$ across treatments. Cousins et al. (2006) suggested that enzymatic activity of CA
434 affects carbon isotope discrimination in most C_4 plants because CA can result in the
435 parameter b_4 changes (see Eq. (2)). But in traditional view, the parameter b_4 was a
436 constant. However, it is only true when the ratio of PEP carboxylation rate to the CO_2
437 hydration rate (V_p/V_h) is equal to zero, which is caused by a high CA activity. If
438 V_p/V_h is not zero, b_4 will change and be controlled by V_p/V_h (Cousins et al., 2006).
439 Previous studies reported that CA activity was low in most C_4 plants (Cousins et al.,
440 2006; Gillon and Yakir, 2000, 2001; Hatch and Burnell, 1990). Thus, CA activity in *H.*

441 *ammodendron* might also be low, leading to the change in b_4 with V_p/V_h , and thus
442 $\delta^{13}\text{C}$. Cousins et al. (2006) added V_p/V_h into the discrimination pattern of C_4 plants
443 and predicted that at a given ϕ value, when the V_p/V_h is 0 or 1, the correlation
444 between Δ and c_i/c_a ratio is negative or positive, respectively. Since CA activity is low
445 in most C_4 plants, and the V_p/V_h always ranges from 0 to 1, we speculate that no
446 correlation between Δ and c_i/c_a ratio may also occur when the V_p/V_h is a certain value
447 between 0 and 1. The irrelevance of Δ and c_i/c_a ratio also means that $\delta^{13}\text{C}_{\text{plant}}$ is not
448 related to c_i/c_a ratio due to the negative correlation between Δ and $\delta^{13}\text{C}_{\text{plant}}$ according
449 to Eq. (2). Thus, the uncorrelated pattern between $\delta^{13}\text{C}$ and c_i/c_a ratio in *H.*
450 *ammodendron* might be related to this specific V_p/V_h value due to low CA activity.

451 In addition, the unchanged $\delta^{13}\text{C}$ across treatments may also be controlled by the
452 water sources of *H. ammodendron*. Previous study has found that the root of *H.*
453 *ammodendron* can be inserted into the soil layer deeper than 3 m (Sheng et al., 2004),
454 which made it easy to uptake groundwater. Therefore, *H. ammodendron* may be less
455 sensitive to water addition. However, a study conducted in the same region has found
456 that the shallow soil water (0-40 cm) and groundwater are two important water
457 sources for *H. ammodendron* (Dai et al., 2014), and another study has reported that
458 water addition resulted in an increase of soil water contents in shallow soil layer (Cui,
459 2018). Moreover, gas exchange changed across treatments in the present study (Fig.
460 2). Thus, the utilization of groundwater by *H. ammodendron* may be one of the
461 reasons why its $\delta^{13}\text{C}$ was not sensitive to water and N addition, but it should not be
462 the main reason.

463 Whether foliar $\delta^{13}\text{C}$ of C_4 plants can indicate their WUE is still controversial.
464 Henderson et al. (1992) found that $\delta^{13}\text{C}$ of 10 C_4 species has negative correlation with
465 their WUE. Although this result was just opposite to a positive relationship between
466 $\delta^{13}\text{C}$ and WUE for C_3 plants ([Farquhar, 1983](#); [Duquesnay et al., 1998](#); [Feng, 1998](#)), it
467 is a proof that $\delta^{13}\text{C}$ of C_4 plants can indicate their WUE. In the work of Henderson et
468 al. (1992), they found that the ϕ values in 10 C_4 species was around 0.21 over a range
469 of irradiance and leaf temperature. According to the suggestion by Cernusak et al.
470 (2013) that Δ is negatively related to c_i/c_a ratio when ϕ value is less than 0.37, thus,
471 the $\delta^{13}\text{C}$ of 10 C_4 species has a positive correlation with c_i/c_a ratio. In general, under
472 fixed ambient CO_2 concentration, WUE is always negatively correlated with c_i/c_a ratio
473 (see Eq. (43) and Eq. (56)). This is why a negative relationship between $\delta^{13}\text{C}$ and
474 WUE was observed for the 10 C_4 species. The present study showed that ins-WUE
475 and int-WUE both had no correlation with $\delta^{13}\text{C}$ in *H. ammodendron* (Fig. 4a, 4c),
476 which was different from the results published by Henderson et al. (1992). In general,
477 c_i/c_a ratio is the link between WUE and $\delta^{13}\text{C}$. As mentioned above, if the ϕ value
478 equals to 0.37 and/or the activity of CA is very low, $\delta^{13}\text{C}$ would not correlate to c_i/c_a
479 ratio, and thus leads to the uncorrelation between $\delta^{13}\text{C}$ and WUE. In addition, the
480 different time scales of $\delta^{13}\text{C}$, ins-WUE and int-WUE may also result in this
481 uncorrelation. As mentioned above, the measured $\delta^{13}\text{C}$ represents the long-term fixed
482 carbon isotope composition (at least several weeks). And the value of ins-WUE and
483 int-WUE were calculated from the gas exchange of a short-term measurement, which
484 lasted only a few minutes. Therefore, this difference in time scale may also drive the

485 uncorrelation between $\delta^{13}\text{C}$ and WUE. Although the defects in measurements could
486 introduce some uncertainty in the observed relationship between $\delta^{13}\text{C}$ and WUE,
487 $\delta^{13}\text{C}$ remained stable under water and nitrogen addition (Fig. 1, Table 1), while the
488 measured ins-WUE and int-WUE was higher in the control treatment (W0N0) than
489 other treatments (Fig. 3), suggesting and water and N supply had a significant effect
490 on WUE (Table 1). These results indirectly confirmed that $\delta^{13}\text{C}$ of *H. ammodendron*
491 could not indicate its WUE.

492 The present study has found that $\delta^{13}\text{C}$ of *H. ammodendron* could not be used as a
493 indicator of its WUE. Although this conclusion cannot be analogous to all C_4 plants,
494 the present study has important implications for the understanding of physiological
495 responses of desert plants to future changes in precipitation and atmospheric N
496 deposition. *H. ammodendron* is a dominant species in Asia desert, which has a great
497 effect on the stabilization of sand dunes, the survival and development of understory
498 plants and the structure and function of desert ecosystems (Sheng et al., 2005; Su et
499 al., 2007; Cui et al., 2017). Thus, *H. ammodendron* is widely distributed in desert
500 areas, and the prediction of its drought adaptation is crucial in desert ecosystem.

501

502 **5 Conclusion**

503 Global changes including precipitation and atmospheric N deposition have been
504 proved to have an important influence on ecosystems, especially for the arid
505 ecosystems. The present study showed that water and N addition had little effect on
506 the $\delta^{13}\text{C}$ values and the degree of bundle-sheath leakiness (ϕ) of *H. ammodendron*, but

507 played an important role in the change of its gas exchange and water use efficiency
508 (WUE). In addition, different pattern of instantaneous WUE (ins-WUE), intrinsic
509 WUE (int-WUE) and $\delta^{13}\text{C}$ across treatment and no correlation between instantaneous
510 WUE (ins-WUE) and $\delta^{13}\text{C}$, and between intrinsic WUE (int-WUE) and $\delta^{13}\text{C}$ has been
511 found in this study, suggesting that $\delta^{13}\text{C}$ of *H. ammodendron* could not indicate its
512 WUE. This result was caused by the lack of the correlation between $\delta^{13}\text{C}$ and the ratio
513 of intercellular to ambient CO_2 concentration (c_i/c_a), which might be associated with
514 the degree of bundle-sheath leakiness (ϕ) or the low activity of carbonic anhydrase
515 (CA). Thus, the current experiment implies that the availability of $\delta^{13}\text{C}$ as the
516 indicator of WUE could be not universal for C_4 species.
