22

23 **Abstract**

24 Variations in precipitation and atmospheric N deposition affect water and N
25 availability in desert, and thus may have significant effects on desert ecosystems.
26 *Haloxylon ammodendron* is a dominant plant in Asian desert, and addressing its
27 physiological acclimatization to the changes in precipitation and N deposition can
28 provide an insight into how desert plants adapt extreme environment by physiological
29 adjustment. Carbon isotope ratio ($\delta^{13}\text{C}$) in plants has been suggested as a sensitive
30 long-term indicator of physiological acclimatization. Therefore, this study evaluated
31 the effect of precipitation change and increasing atmospheric N deposition on $\delta^{13}\text{C}$ of
32 *H. ammodendron*. Furthermore, *Haloxylon ammodendron* is a C_4 plant, whether its
33 $\delta^{13}\text{C}$ can indicate water use-efficiency (WUE) has not been addressed. In the present
34 study, we designed a field experiment with a completely randomized factorial
35 combination of N and water, and measured $\delta^{13}\text{C}$ and gas exchange, then we calculated
36 the degree of bundle-sheath leakiness (ϕ) and WUE of the assimilating branches of *H.*
37 *ammodendron*. $\delta^{13}\text{C}$ and ϕ in *H. ammodendron* remained stable under N and water
38 supply, while N addition, water addition and their interaction affected gas exchange
39 and WUE in *H. ammodendron*. In addition, $\delta^{13}\text{C}$ had no correlation with WUE. These
40 results are associated with the irrelevance between $\delta^{13}\text{C}$ and the ratio of intercellular
41 to ambient CO_2 concentration (c_i/c_a), which might be caused by a special value (0.37)
42 of the degree of bundle-sheath leakiness (ϕ) or a lower activity of carbonic anhydrase
43 (CA) of *H. ammodendron*. In conclusion, $\delta^{13}\text{C}$ of *H. ammodendron* is insensitive to
44 global change in precipitation and atmospheric N deposition, and cannot be used for

45 indicating its WUE.

46

47 **1 Introduction**

48 Recently, global precipitation pattern has changed significantly (Frank et al., 2015;
49 Knapp et al., 2015), and atmospheric N deposition has continued to rise (Galloway et
50 al., 2004; Liu et al., 2013; Song et al., 2017). Previous researchers have suggested that
51 arid ecosystems are most sensitive to climate change (Reynolds et al., 2007; Huang et
52 al., 2016), while global change in precipitation and atmospheric N deposition has an
53 important impact on water and N availability in desert (Huang et al., 2018). Thus,
54 these changes may have significant effects on desert ecosystems. *Haloxylon*
55 *ammodendron* is a dominant species in desert regions, especially in Asia. Studying the
56 physiological responses of *H. ammodendron* to global change can provide an insight
57 into how desert plants adapt extreme environment by physiological adjustment.
58 Carbon isotope ratio ($\delta^{13}\text{C}$) in plants depends on the ratio of intercellular to ambient
59 CO_2 concentration (c_i/c_a), which reflects the balance between inward CO_2 diffusion
60 rate, regulated by stomatal conductance (g_s), and CO_2 assimilating rate (A) (Farquhar
61 and Richards, 1984), and has been suggested as a sensitive long-term indicator of
62 physiological acclimatization (Battipaglia et al., 2013; Cernusak et al., 2013; Tranan
63 and Schubertt, 2016; Wang and Feng, 2012). Therefore, investigating the variations in
64 $\delta^{13}\text{C}$ of *H. ammodendron* under water and nitrogen addition can enhance
65 understanding of physiological responses of desert plants to future changes in
66 precipitation and atmospheric N deposition.

67 A large quantity of works has been devoted to the relationships between C₃ plant
68 $\delta^{13}\text{C}$ and water availability or precipitation (e.g., Diefendorf et al., 2010; Kohn, 2010;
69 Liu et al., 2005; Ma et al., 2012; Serret et al., 2018; Stewart et al., 1995; Wang et al.,
70 2005, 2008) and nitrogen availability (e.g. Cernusak et al., 2007; Li et al., 2016;
71 Sparks and Ehleringer, 1997; Yao et al., 2011; Zhang et al., 2015). However, a
72 relatively small amount of research has focused on the responses of C₄ plant $\delta^{13}\text{C}$ to
73 water availability or precipitation (Ellsworth et al., 2017; Liu et al., 2005; Rao et al.,
74 2017; Wang et al., 2006) and nitrogen availability (Ma et al., 2016; Schmidt et al.,
75 1993). For C₄ plants, $\delta^{13}\text{C}$ is controlled by both the c_i/c_a ratio and the degree of
76 bundle-sheath leakiness (ϕ), the proportion of CO₂ produced within bundle sheath
77 cells from C₄ acids that leaks back to mesophyll cells (Ellsworth and Cousins, 2016;
78 Ellsworth et al., 2017; Farquhar, 1983). Thus, the responses of C₄ plant $\delta^{13}\text{C}$ to water
79 and N availability are also affected by ϕ . Genetic factors control ϕ values, which
80 causes the interspecific differences in $\delta^{13}\text{C}$, even the responses of plant $\delta^{13}\text{C}$ to water
81 and N availability (Gresset et al., 2014). On the other hand, enzymatic activity of
82 carbonic anhydrase (CA) may influence $\delta^{13}\text{C}$ in C₄ plants as CA activity is low
83 (Cousins et al., 2006). CA is an enzyme that catalyzes the hydration of CO₂ in
84 mesophyll cells to form bicarbonate (HCO₃⁻). Previous studies showed that CA
85 activity in most C₄ plants is usually low, just sufficient to support photosynthesis
86 (Cousins et al., 2006; Gillon and Yakir, 2000, 2001; Hatch and Burnell, 1990). *H.*
87 *ammodendron* is a typical C₄ plant. How its $\delta^{13}\text{C}$ responds to water and N availability
88 has never been addressed.

89 Foliar $\delta^{13}\text{C}$ in C_3 plants has been considered as a useful indicator of intrinsic water
90 use-efficiency (WUE) (Farquhar, 1983). However, although some studies suggested
91 that $\delta^{13}\text{C}$ of C_4 plants could also indicate its WUE (Henderson et al., 1992; Wang et al.,
92 2005; Cernusak et al., 2013; Ellsworth and Cousins, 2016), this statement is still
93 controversial. The relationship between $\delta^{13}\text{C}$ and WUE is based on the links between
94 c_i/c_a ratio and $\delta^{13}\text{C}$ and between c_i/c_a ratio and WUE (Ehleringer and Cerling, 1995).
95 For C_3 plants, $\delta^{13}\text{C}$ always decreases with an increase in c_i/c_a ratio; but for C_4 plants,
96 the correlation between $\delta^{13}\text{C}$ and c_i/c_a ratio depends on ϕ value (Cernusak et al., 2013)
97 and CA activity (Cousins et al., 2006). As mentioned above, ϕ value is under genetic
98 control, and the CA activity changes across species (Cousins et al., 2006; Gillon and
99 Yakir, 2000, 2001; Hatch and Burnell, 1990), thus, the correlation between $\delta^{13}\text{C}$ and
100 c_i/c_a ratio, as well as the relationship between WUE and $\delta^{13}\text{C}$, shows interspecific
101 difference. Whether $\delta^{13}\text{C}$ of *H. ammodendron* indicates WUE has never been
102 evaluated.

103 In this study, we designed an experiment with multiple water and nitrogen supply in
104 the southern Gurbantunggut Desert in Xinjiang Uygur Autonomous Region, China.
105 We measured the $\delta^{13}\text{C}$, gas exchange and WUE of the assimilating branches of *H.*
106 *ammodendron*. We had two objectives. One objective was to evaluate the response of
107 the dominant plant of Asian desert to future changes in precipitation and atmospheric
108 N deposition by revealing the effects of water and N supply on $\delta^{13}\text{C}$ of *H.*
109 *ammodendron*. The other was to explore the availability of $\delta^{13}\text{C}$ as the indicator of
110 water use-efficiency in *H. ammodendron*.

111

112 **2 Materials and methods**

113 **2.1 Definitions and Basic Equations**

114 Stable carbon isotopic ratio ($\delta^{13}\text{C}$) of natural materials is expressed as:

$$115 \quad \delta^{13}\text{C}(\text{‰}) = \left[\frac{(^{13}\text{C}/^{12}\text{C})_{\text{sample}}}{(^{13}\text{C}/^{12}\text{C})_{\text{standard}}} - 1 \right] \times 1000 \quad (1)$$

116 where the standard is the carbon dioxide obtained from the Peedee belemnite (PDB)
117 limestone (Craig, 1957). Farquhar (1983) proposed the pattern of carbon isotopic
118 discrimination (Δ) in C_4 plant:

$$119 \quad \Delta = \frac{\delta^{13}\text{C}_{\text{air}} - \delta^{13}\text{C}_{\text{plant}}}{1 + \delta^{13}\text{C}_{\text{plant}}/1000} \approx \delta^{13}\text{C}_{\text{air}} - \delta^{13}\text{C}_{\text{plant}} = a + [b_4 + \varphi (b - s) - a] \frac{c_i}{c_a} \quad (2)$$

120 where $\delta^{13}\text{C}_{\text{plant}}$ and $\delta^{13}\text{C}_{\text{air}}$ are the $\delta^{13}\text{C}$ values of plants and CO_2 in the ambient air. The
121 parameter a ($= 4.4\text{‰}$, Craig, 1954) is the carbon isotopic fractionation in the diffusion
122 of CO_2 into internal leaves; b_4 ($= -5.9\text{‰}$, O'Leary, 1984) is the combined carbon
123 isotopic fractionations occurring in the processes of gaseous CO_2 dissolution,
124 hydration/dehydration reactions of CO_2 and HCO_3^- in mesophyll cells, and
125 HCO_3^- carboxylation by PEP (phosphoenolpyruvate) carboxylase; s ($= 1.8\text{‰}$, O'Leary,
126 1984) is the carbon isotopic fractionation during diffusion of CO_2 out of the
127 bundle-sheath cells, and b ($= 27\text{‰}$, Farquhar and Richards, 1984) is the carbon
128 isotopic fractionation of CO_2 carboxylation by RuBP (ribulose-1,5-bisphosphate)
129 carboxylase. The variable φ is the proportion of CO_2 producing within bundle sheath
130 cells from C_4 acids that leaks back to mesophyll cells, and c_i/c_a is the ratio of
131 intercellular to ambient CO_2 concentration.

132 Water use-efficiency (WUE) is defined as the amount of assimilated carbon dioxide

133 by plants under the consumption of per unit water. There are two characteristics of
134 WUE, instantaneous WUE (ins-WUE) and intrinsic WUE (int-WUE), respectively.

135 ins-WUE can be calculated by:

$$136 \quad \text{ins-WUE} = A/E = (c_a - c_i)/1.6v = c_a(1 - c_i/c_a)/1.6v \quad (3)$$

137 where A is photosynthetic rate, E is transpiration rate and v is calculated

138 by:

$$139 \quad v = (e_i - e_a)/p \quad (4)$$

140 where e_i and e_a are the water vapor pressure inside and outside the leaves, p is the

141 atmospheric pressure.

142 The definition of int-WUE is:

$$143 \quad \text{int-WUE} = A/g_s = (c_a - c_i)/1.6 = c_a(1 - c_i/c_a)/1.6 \quad (5)$$

144 where g_s is stomatal conductance.

145 **2.2 Study site**

146 This experiment was conducted at the Fukang Station of Desert Ecology, Chinese
147 Academy of Sciences, on the southern edge of the Gurbantunggut Desert (44°26' N,
148 87°54' E) in northwestern China. The altitude of the study site is 436.8 m above
149 average sea level (a.s.l.). It is a typical continental arid, temperate climate, with a hot
150 summer and cold winter in the area. The mean annual temperature is 7.1°C and the
151 mean annual precipitation is 215.6 mm, with a potential evaporation of about 2000
152 mm. The mean annual temperature and the annual rainfall amount in the sampling
153 year are 10.23°C and 122.7 mm (Cui, 2018). The soil type is grey desert soils
154 (Chinese classification) with aeolian sands on the surface (0-100 cm). The

155 percentages of clay (< 0.005 mm), silt (0.005-0.063 mm), fine sand (0.063-0.25 mm)
156 and medium sand (0.25-0.5 mm) range from 1.63-1.76%, 13.79-14.15%,
157 55.91-56.21% and 20.65-23.23%, respectively (Chen et al., 2007). The soil is highly
158 alkaline ($\text{pH} = 9.55 \pm 0.14$) with low fertility. The vegetation is dominated by
159 *Haloxylon ammodendron* and *Haloxylon persicum* with about 30% coverage. Herbs
160 include ephemerals, annuals and small perennials, with a cover of ca. 40% (Fan et al.,
161 2013). Although the coverage of the two *Haloxylon* species is a little lower than that
162 of herbs, the biomass of the former is much larger than that of the latter, because
163 *Haloxylon* plants are shrubs with an average height of 1.5 m whereas the latter are
164 very low herbaceous plants. Biological soil crusts are distributed widely on the soil
165 between the herbs and *Haloxylon*, with almost 40% coverage (Zhang et al., 2007).

166 **2.3 Experimental design**

167 A field experiment with a completely randomized factorial combination of water and
168 nitrogen has been conducted from 2014 to 2017. We designed two water addition
169 levels (0, $60\text{mm}\cdot\text{yr}^{-1}$; W0, W1), since precipitation is predicted to increase by 30% in
170 northern China in the next 30 years (Liu et al., 2010), and three levels of N addition (0,
171 30, 60 $\text{kg N}\cdot\text{ha}^{-1}\cdot\text{yr}^{-1}$; N0, N1 and N2), because N deposition has reached 35.4 kg
172 $\text{N}\cdot\text{ha}^{-1}\cdot\text{yr}^{-1}$ in the nearby city, Urumqi (Cui et al., 2017) and will double by 2050
173 relative to the early 1990s (Galloway et al., 2008). Therefore, there were six
174 treatments (W0N0, W0N1, W0N2, W1N0, W1N1, W1N2) in this experiment. Four
175 replicates of each treatment were set, making a total of 24 plots with a size of 10 m
176 \times 10 m. A small sub-plot with a size of 1.5 m \times 1.5 m was set in each plot. A

177 well-grown *H. ammodendron* was enclosed in the center of the sub-plot. The average
178 height and coverage of an individual *H. ammodendron* were 1.5 m and 1.9 m²,
179 respectively, and did not vary significantly across the plots. To simulate natural water
180 and N inputs, the treatments were applied in equal amounts, twelve times, once a
181 week in April, July and September, as 5 mm·m⁻² of water and 2.5 or 5 kg N·ha⁻¹ each
182 week (Cui et al., 2017). Usually, water addition was with a sprinkler kettle, irrigating
183 over the canopy of *H. ammodendron*.

184 **2.4 Measurements of gas exchange traits and WUE**

185 The leaves of *H. ammodendron* have been completely degraded due to the extreme
186 drought, and the assimilation branches perform the same functions as the leaves. Thus,
187 we conducted gas exchange measurements on the assimilation branches of the *H.*
188 *ammodendron* grown in the sub-plots by LI-6400 portable photosynthesis system on
189 27-29, June 2016. The ins-WUE and the int-WUE were calculated based on these
190 measured gas exchange traits by the Eq. (3), and int-WUE by Eq. (5). At each plot,
191 the top assimilating branches of a mature individual was selected randomly for the
192 measurement. About 5s was needed for stability after the assimilating branches was
193 inserted in the cuvette and then the assimilating branches were measured. We
194 repeated 10 times on the same assimilating branches for each measurement. We
195 measured gas exchange with a standard 450 mmol·mol⁻¹ CO₂ concentration at a flow
196 rate of 500 mmol·s⁻¹ above saturation in photo flux density of 1600 mmol·m⁻²·s⁻¹. The
197 temperature of the measuring assimilating branches varied from 29.5 °C to 30.5 °C
198 during the entire period of gas exchange measurements.

199 **2.5 Samples collection**

200 Considering that there is a considerable difference in $\delta^{13}\text{C}$ between buds, young and
201 matured leaves, so we collected the mature assimilating branches of *H. ammodendron*
202 for the $\delta^{13}\text{C}$ measurements. All *H. ammodendron* individuals grown in plots (10 m \times
203 10 m) were sampled. Eight pieces of the mature assimilating branches were collected
204 from each individual, two pieces of assimilating branches were collected at each of
205 the four cardinal directions from the positions of full irradiance. All assimilating
206 branches from the same plot were combined into one sample. All plant samples were
207 air-dried in the field and then in the laboratory. Then the samples were ground into a
208 fine powder using a steel ball mixer mill MM200 (Retsch GmbH, Haan, Germany) for
209 the measurements of $\delta^{13}\text{C}$, N contents and chlorophyll contents.

210 **2.6 Measurements of plant $\delta^{13}\text{C}$, plant N and chlorophyll contents**

211 The $\delta^{13}\text{C}$ and N measurements were performed on a Delta^{Plus} XP mass spectrometer
212 (Thermo Scientific, Bremen, Germany) coupled with an automated elemental
213 analyzer (Flash EA1112, CE Instruments, Wigan, UK) in a continuous flow mode, at
214 the Stable Isotope Laboratory of the College of Resources and Environmental
215 Sciences, China Agricultural University. The carbon isotopic ratios were reported in
216 the delta notation relative to the V-PDB standard. For this measurement, we obtained
217 standard deviations low than 0.15‰ for $\delta^{13}\text{C}$ among replicate measurements of the
218 same sample. And standard deviations for the N measurements were 0.1%.

219 The chlorophyll contents of all samples were also determined. The samples were
220 first extracted by 95% ethyl alcohol (0.5 g sample to 25 mL ethyl alcohol), and then

221 the absorbancy was measured under the wave length of 665 and 649 nm by the
222 spectrophotometer. The content of chlorophyll a, b was calculated by the follow
223 equations:

$$224 \quad \text{Chlorophyll a (mg/L)} = 13.95 \times \text{OD}_{665} - 6.88 \times \text{OD}_{649} \quad (6)$$

$$225 \quad \text{Chlorophyll b (mg/L)} = 24.96 \times \text{OD}_{649} - 7.32 \times \text{OD}_{665} \quad (7)$$

226 where OD₆₆₅ and OD₆₄₉ are the absorbancy under the wave length of 665 and
227 649nm, respectively.

228 **2.6 Calculation of the degree of bundle-sheath leakiness**

229 The degree of bundle-sheath leakiness (ϕ) was calculated by the transformation of Eq.
230 (2):

$$231 \quad \phi = \left(\frac{(\delta^{13}\text{C}_{\text{air}} - \delta^{13}\text{C}_{\text{plant}}) / (1 + \delta^{13}\text{C}_{\text{plant}}/1000) - a}{c_i/c_a} + a - b_4 \right) / (b - s) \quad (8)$$

232 In this equation, parameters a, b₄, b and s are constant, while $\delta^{13}\text{C}_{\text{plant}}$ and c_i/c_a are
233 the measured values of our samples. We did not measure the $\delta^{13}\text{C}_{\text{air}}$ at our study site,
234 so we had to use an approximation of the $\delta^{13}\text{C}_{\text{air}}$ to do this ϕ calculation. The
235 approximated value we used is -9.77‰, which has been measured at Donglingshan
236 Mountain, Beijing, north China in September 2019. We believe that the two sites
237 should have similar $\delta^{13}\text{C}_{\text{air}}$ because the two sites are located in countryside with less
238 human activities and have a similar distance from the nearest city. The straight line
239 distances between Donglingshan Mountain and the city center of Beijing, and
240 between our study site and Urumqi city are about 90 km.

241 **2.7 Statistical analysis**

242 Statistical analyses were conducted using SPSS software (SPSS for Windows, Version

243 20.0, Chicago, IL, United States). One-way analysis of variance (ANOVA) and
244 two-way analysis of variance (ANOVA) were used to compare the difference of $\delta^{13}\text{C}$
245 and other physiological traits between each treatment. Pearson analysis was used to
246 determine the correlation among $\delta^{13}\text{C}$, WUE and c_i/c_a in *H. ammodendron*.

247

248 **3 Results**

249 **3.1 Plant $\delta^{13}\text{C}$ under water and nitrogen addition**

250 The $\delta^{13}\text{C}$ of the assimilating branches of *H. ammodendron* in the six treatments
251 W0N0, W0N1, W0N2, W1N0, W1N1, W1N2 was $-14.18 \pm 0.19 \text{ ‰}$, $-14.71 \pm 0.35 \text{ ‰}$,
252 $-14.45 \pm 0.18 \text{ ‰}$, $-14.67 \pm 0.40 \text{ ‰}$, $-14.65 \pm 0.38 \text{ ‰}$, $-14.34 \pm 0.29 \text{ ‰}$, respectively.

253 One-way ANOVA analyses showed no significant variation in $\delta^{13}\text{C}$ across treatments
254 ($p = 0.788$, Fig. 1). Two-way ANOVA analyses suggested that $\delta^{13}\text{C}$ was not affected
255 by water addition ($p = 0.678$), N addition ($p = 0.607$) and their interaction ($p = 0.563$,
256 Table 1).

257 Fig.1

258 Table 1

259 **3.2 Gas exchange and WUE under water and nitrogen addition**

260 Photosynthetic rate (A), stomatal conductance (g_s), transpiration rate (E) and c_i/c_a
261 ranged from $12.11 \mu\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$ to $39.35 \mu\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$, from $0.09 \text{ mol H}_2\text{O}$
262 $\text{m}^{-2} \text{ s}^{-1}$ to $0.31 \text{ mol H}_2\text{O m}^{-2} \text{ s}^{-1}$, from $2.87 \text{ mmol H}_2\text{O m}^{-2} \text{ s}^{-1}$ to $8.49 \text{ mmol H}_2\text{O m}^{-2} \text{ s}^{-1}$
263 and 0.11 to 0.57, respectively. One-way ANOVA analyses showed significant changes
264 in leaf gas exchange across the six treatments ($p = 0.012$ for A, $p = 0.006$ for g_s , $p =$

265 0.002 for E and c_i/c_a , Fig. 2). Two-way ANOVA analyses suggested that water
266 addition had exerted effect on c_i/c_a ($p = 0.004$), that N additions influenced A ($p =$
267 0.008) and c_i/c_a ($p = 0.009$), and that the interaction between water and N supply
268 played a role in g_s ($p < 0.001$), E ($p < 0.001$) and c_i/c_a ($p < 0.001$, Table 1).

269 Fig. 2

270 Instantaneous WUE (ins-WUE) and intrinsic WUE (int-WUE) ranged from 3.09
271 $\mu\text{mol CO}_2 / \text{mmol H}_2\text{O}$ to $8.49\mu\text{mol CO}_2 / \text{mmol H}_2\text{O}$ and from $93.64\mu\text{mol CO}_2 / \text{mol}$
272 H_2O to $208.47\mu\text{mol CO}_2 / \text{mmol H}_2\text{O}$, respectively. One-way ANOVA analyses
273 showed significant changes in these two indexes (both $p < 0.001$, Fig. 3). Two-way
274 ANOVA analyses suggested that water addition, N addition and their interaction all
275 have significant effect on these two indexes (all $p < 0.05$, Table 1).

276 Fig. 3

277 **3.3 Correlations among $\delta^{13}\text{C}$, WUE and c_i/c_a ratio**

278 In order to test whether $\delta^{13}\text{C}$ in *H. ammodendron* can indicate WUE, the relationships
279 among $\delta^{13}\text{C}$, ins-WUE, int-WUE and c_i/c_a ratio were revealed in this study. Our
280 results showed no correlation between $\delta^{13}\text{C}$ and ins-WUE ($p = 0.229$, Fig. 4a),
281 between $\delta^{13}\text{C}$ and int-WUE ($p = 0.229$, Fig. 4c), and between $\delta^{13}\text{C}$ and c_i/c_a ratio ($p =$
282 0.183 , Fig. 4e). However, there was a negative correlation between ins-WUE and c_i/c_a
283 ratio ($p < 0.001$, Fig. 4b), and between int-WUE and c_i/c_a ratio ($p < 0.001$, Fig. 4d).

284 Fig. 4

285 **3.4 The degree of bundle-sheath leakiness under water and nitrogen addition**

286 The calculated ϕ ranged from 0.32 to 0.59 with a mean value of 0.45. One-way

287 ANOVA analyses showed no significant variation in ϕ across treatments ($p = 0.768$,
288 Fig. 5). Two-way ANOVA analyses suggested that $\delta^{13}\text{C}$ was not affected by water
289 addition ($p = 0.644$), N addition ($p = 0.600$) and their interaction ($p = 0.521$, Table 1).

290 Fig. 5

291

292 **4 Discussion**

293 The $\delta^{13}\text{C}$ of the assimilating branches in *H. ammodendron* did not change across
294 treatments (Fig. 1, Table 1), suggesting that neither water addition nor nitrogen
295 addition influenced the $\delta^{13}\text{C}$ of *H. ammodendron*. Previous studies also reported no
296 significant relationship between $\delta^{13}\text{C}$ of C_4 plant and water availability (Swap et al.,
297 2004; Wang et al., 2008), and between $\delta^{13}\text{C}$ of C_4 plant and nitrogen availability (Yao
298 et al., 2011, Yang et al., 2017).

299 In general, the effects of water availability and nitrogen availability on $\delta^{13}\text{C}$ are
300 dependent on c_i/c_a ratio, which reflects the balance between stomatal conductance (g_s)
301 and photosynthetic rate (A) (Farquhar and Richards, 1984). With more water
302 availability under water addition, plants tend to open stomata to absorb more CO_2 ,
303 leading to an increase in g_s . Two-way ANOVA analyses suggested that water addition
304 had no effect on both A and g_s (Table 1). However, One-way ANOVA analyses
305 showed that g_s was higher in W1N0 than that in W0N0 (Fig. 2b). Thus, at least water
306 addition had a positive effect on g_s under ambient N condition. Increasing g_s under
307 water supply will lead to the rise of intercellular CO_2 because of the decrease of
308 diffusional resistance to CO_2 . As the results, c_i/c_a ratio was observed to increase with

309 increasing moisture (Fig. 2d, Table 1). However, $\delta^{13}\text{C}$ remained stable under water
310 addition (Fig. 1, Table 1). Thus, c_i/c_a ratio could not explain the observed response of
311 $\delta^{13}\text{C}$ to water supply.

312 For most plants in natural ecosystems, nitrogen is the key factor limiting plant
313 growth (Hall et al., 2011). Thus, nitrogen addition usually causes plants to absorb
314 more N. However, extreme drought could prevent plants from absorbing N even
315 under high N supply. In the present experiment, N supply was found to have an effect
316 on N contents in *H. ammodendron*. Relative to the control treatment (W0N0), N
317 contents increased with N supply under low N addition, but kept unchanged under
318 high addition (Table S1, S2). Nitrogen is the main constituent of Rubisco (ribulose -
319 1,5 - bisphosphate carboxylase oxygenase) and chlorophyll in plants. Thus,
320 chlorophyll a was found to have the similar pattern as N contents under water and N
321 supply. Chlorophyll a was higher in W0N1 than W0N0, and there was no difference in
322 chlorophyll a between W0N0 and W0N2 (Table S1). Increasing chlorophyll contents
323 in W0N1 should lead to the increase in photosynthetic rate (A). However, different
324 from our prediction, one-way ANOVA analyses suggested that A in W0N1 did not
325 differ from that in W0N0, and that A in W0N2 is lower than that in W0N0 (Fig., 2a).
326 Two-way ANOVA analyses showed that N addition had an influence on A (Table 1).
327 Both the analyses suggested that N supply played a negative role in A, and thus the
328 consumption of intercellular CO_2 . Consequently, c_i/c_a ratio was found to increase with
329 N supply (Fig. 2d, Table 1). Therefore, the variations in c_i/c_a ratio with N addition
330 could not account for the unchanged pattern in $\delta^{13}\text{C}$ under N supply (Fig. 1).

331 The co-application of water and nitrogen was found to have a negative effect on A
332 but no effect on g_s (W0N0 vs. W1N1, W1N2, Fig. 2a, b). The responses of A and g_s to
333 the co-application of water and nitrogen resulted in an increase in c_i/c_a ratio (Fig., 2d).
334 Since $\delta^{13}\text{C}$ remained unchanged under the co-application of water and nitrogen (Fig.
335 1), c_i/c_a ratio could not also explain the observed $\delta^{13}\text{C}$ response to the co-application
336 of water and nitrogen.

337 In summary, the unchanged $\delta^{13}\text{C}$ across treatments did not related to c_i/c_a ratio in *H.*
338 *ammodendron*, and we did find that there is no correlation between $\delta^{13}\text{C}$ and the
339 measured c_i/c_a ratio (Fig. 4e). Thereby, the observed $\delta^{13}\text{C}$ stability across treatments
340 may be associated with the ϕ value and carbonic anhydrase (CA) in *H. ammodendron*.
341 For C_4 plants, the relationship between carbon isotope discrimination (Δ) and c_i/c_a
342 ratio is dependent on ϕ values (Ellsworth and Cousins, 2016; Ellsworth et al., 2017;
343 Farquhar, 1983; Wang et al., 2008). Some studies suggested that ϕ value was stable
344 for a given species under a wide range of environmental conditions (Henderson et al.,
345 1992; Wang et al., 2008; Cernusak et al., 2013). However, other studies had different
346 conclusions that ϕ value was influenced by irradiation (Bellasio and Griffiths, 2014;
347 Kromdijk et al., 2010; Pengelly et al., 2010; Ubierna et al., 2013), temperature (von
348 Caemmerer et al., 2014), water stress (Fravolini et al., 2002; Gong et al., 2017;
349 Williams et al., 2001; Yang et al., 2017) and nitrogen supply (Fravolini et al., 2002;
350 Meinzer and Zhu, 1998; Yang et al., 2017). In current study, the ϕ value of *H.*
351 *ammodendron* remained unchanged across six treatments (Fig. 5), and two-way
352 ANOVA analyses suggested that water supply and N supply had no effect on ϕ (Table

353 1). Therefore, the ϕ value of *H. ammodendron* was insensitive to water and N addition
354 in this study. Even if the ϕ value remains stable, the relationship between Δ and c_i/c_a
355 ratio is also associated with the magnitude of the ϕ value. Cernusak et al. (2013)
356 predicted that when ϕ value is greater than 0.37, the correlation between Δ and c_i/c_a
357 ratio is positive; conversely, when ϕ value is less than 0.37, the correlation is negative.
358 In particular, when ϕ value is equal to 0.37, no significant correlation can be found,
359 because the coefficient ($[b_4 + \phi (b - s) - a]$ in Eq. (2)) of c_i/c_a ratio equals to 0
360 (Cernusak et al., 2013). The ϕ value ranged from 0.32 to 0.59 with a mean value of
361 0.45 in present study. Thus, the correlation between Δ and c_i/c_a in *H. ammodendron*
362 should be positive based on the prediction by Cernusak et al. (2013). It seems that ϕ is
363 not the driver of the observed $\delta^{13}\text{C}$ pattern in *H. ammodendron*. However, there were
364 some uncertainties in the calculation of ϕ value based on the measured $\delta^{13}\text{C}$ and c_i/c_a .
365 The measured $\delta^{13}\text{C}$ represents the fixed carbon isotope composition throughout the
366 assimilation branch formation period, which usually spans at least several weeks. And
367 the measured c_i/c_a is a instant indicator. Therefore, the ϕ value of *H. ammodendron*
368 may be close to 0.37, which led to the observed insensitive response of $\delta^{13}\text{C}$ to
369 water and N addition.

370 The enzymatic activity of CA may be another mechanism behind the unchanged
371 $\delta^{13}\text{C}$ across treatments. Cousins et al. (2006) suggested that enzymatic activity of CA
372 affects carbon isotope discrimination in most C_4 plants because CA can result in the
373 changing of parameter b_4 (see Eq. (2)). But in traditional view, the parameter b_4 was a
374 constant. However, it is only true when the ratio of PEP carboxylation rate to the CO_2

375 hydration rate (V_p/V_h) is equal to zero, which is caused by a high CA activity. If
376 V_p/V_h is not zero, b_4 will change and be controlled by V_p/V_h (Cousins et al., 2006).
377 Previous studies reported that CA activity is low in most C_4 plants (Cousins et al.,
378 2006; Gillon and Yakir, 2000, 2001; Hatch and Burnell, 1990). Thus, CA activity in *H.*
379 *ammodendron* might also be low, leading to the change in b_4 with V_p/V_h , and thus
380 $\delta^{13}C$. Cousins et al. (2006) added V_p/V_h into the discrimination pattern of C_4 plants
381 and predicted that at a given ϕ value, when the V_p/V_h is 0 or 1, the correlation
382 between Δ and c_i/c_a ratio is negative or positive, respectively. Since CA activity is low
383 in most C_4 plants, and the V_p/V_h always ranges from 0 to 1, we speculate that no
384 correlation between Δ and c_i/c_a ratio may also occur when the V_p/V_h is a certain value
385 between 0 and 1. Thus, the uncorrelated pattern between Δ and c_i/c_a ratio in *H.*
386 *ammodendron* might be related to this specific V_p/V_h value due to low CA activity.

387 In addition, the unchanged $\delta^{13}C$ across treatments may also be controlled by the
388 water sources of *H. ammodendron*. Previous study has found that the root of *H.*
389 *ammodendron* can be inserted into the soil layer deeper than 3 m (Sheng et al., 2004),
390 which made it easy to uptake groundwater. Therefore, *H. ammodendron* may be less
391 sensitive to water addition. However, a study conducted in the same region has found
392 that the shallow soil water (0-40 cm) and groundwater are two important water
393 sources for *H. ammodendron* (Dai et al., 2014), and another study has reported that
394 water addition resulted in an increase of soil water contents in shallow soil layer (Cui,
395 2018). Moreover, gas exchange changed across treatments in the present study (Fig.
396 2). Thus, the utilization of groundwater by *H. ammodendron* may be one of the

397 reasons why its $\delta^{13}\text{C}$ is not sensitive to water and N addition, but it should not be the
398 main reason.

399 Whether foliar $\delta^{13}\text{C}$ of C_4 plants can indicate their WUE is still controversial.
400 Henderson et al. (1992) found that $\delta^{13}\text{C}$ of 10 C_4 species has negative correlation with
401 their WUE. Although this result was just opposite to a positive relationship between
402 $\delta^{13}\text{C}$ and WUE for C_3 plants, it is a proof that $\delta^{13}\text{C}$ of C_4 plants can indicate their
403 WUE. In the work of Henderson et al. (1992), they found that the ϕ values in 10 C_4
404 species was around 0.21 over a range of irradiance and leaf temperature. According to
405 the suggestion by Cernusak et al. (2013) that Δ is negatively related to c_i/c_a ratio when
406 ϕ value is less than 0.37, thus, the $\delta^{13}\text{C}$ of 10 C_4 species has a positive correlation with
407 c_i/c_a ratio. In general, under fixed ambient CO_2 concentration, WUE is always
408 negatively correlated with c_i/c_a ratio (see Eq. (3) and Eq. (5)). This is why a negative
409 relationship between $\delta^{13}\text{C}$ and WUE was observed for the 10 C_4 species. The present
410 study showed that ins-WUE and int-WUE both had no correlation with $\delta^{13}\text{C}$ in *H.*
411 *ammmodendron* (Fig. 4a, 4c), which was different from the results published by
412 Henderson et al. (1992). In general, c_i/c_a ratio is the link between WUE and $\delta^{13}\text{C}$. As
413 mentioned above, if the ϕ value equals to 0.37 and/or the activity of CA is very low,
414 $\delta^{13}\text{C}$ would not correlate to c_i/c_a ratio, and thus leads to the uncorrelation between
415 $\delta^{13}\text{C}$ and WUE. In addition, the different time scales of $\delta^{13}\text{C}$, ins-WUE and int-WUE
416 may also result in this uncorrelation. As mentioned above, the measured $\delta^{13}\text{C}$
417 represents the long-term fixed carbon isotope composition (at least several weeks).
418 And the value of ins-WUE and int-WUE were calculated from the gas exchange of a

419 short-term measurement, which lasted only a few minutes. Therefore, this difference
420 may also drive the uncorrelation between $\delta^{13}\text{C}$ and WUE. In other word, there should
421 be a correlation between WUE and $\delta^{13}\text{C}$ in *H. ammodendron*, and the obtained results
422 was only caused by the uncertainty of the experiment. However, $\delta^{13}\text{C}$ remained stable
423 under water and nitrogen addition (Fig. 1, Table 1), while the measured ins-WUE and
424 int-WUE was higher in the control treatment (W0N0) than other treatments (Fig. 3),
425 suggesting and water and N supply had a significant effect on WUE (Table 1). As a
426 result, although there are some uncertainties in the relationship between $\delta^{13}\text{C}$ and
427 WUE, our results indirectly confirmed that $\delta^{13}\text{C}$ of *H. ammodendron* could not
428 indicate its WUE.

429 The present study has found that $\delta^{13}\text{C}$ of *H. ammodendron* could not be used as a
430 indicator of its WUE. Although this conclusion cannot be analogous to all C_4 plants,
431 the present study has important implications for the understanding of physiological
432 responses of desert plants to future changes in precipitation and atmospheric N
433 deposition. *H. ammodendron* is a dominant species in Asia desert, which has a great
434 effect on the stabilization of sand dunes, the survival and development of understory
435 plants and the structure and function of desert ecosystems (Sheng et al., 2005; Su et
436 al., 2007; Cui et al., 2017). Thus, *H. ammodendron* is widely distributed in desert
437 areas, and the prediction of its drought adaptation is crucial in desert ecosystem.

438

439 **5 Conclusion**

440 Global changes including precipitation and atmospheric N deposition have been

441 proved to have an important influence on ecosystems, especially for the arid
442 ecosystems. The present study showed that water and N addition had little effect on
443 the $\delta^{13}\text{C}$ values and the degree of bundle-sheath leakiness (ϕ) of *H. ammodendron*, but
444 played an important role in the change of its gas exchange and water use efficiency
445 (WUE). In addition, different pattern of instantaneous WUE (ins-WUE), intrinsic
446 WUE (int-WUE) and $\delta^{13}\text{C}$ across treatment and no correlation between instantaneous
447 WUE (ins-WUE) and $\delta^{13}\text{C}$, and between intrinsic WUE (int-WUE) and $\delta^{13}\text{C}$ has been
448 found in this study, suggesting that $\delta^{13}\text{C}$ of *H. ammodendron* could not indicate its
449 WUE. This result is caused by the lack of the correlation between $\delta^{13}\text{C}$ and the ratio
450 of intercellular to ambient CO_2 concentration (c_i/c_a), which might be associated with
451 the degree of bundle-sheath leakiness (ϕ) or the low activity of carbonic anhydrase
452 (CA). Thus, the current experiment implies that the availability of $\delta^{13}\text{C}$ as the
453 indicator of WUE could be not universal for C_4 species.
