Abstract. Headspace analysis of CO₂ frequently has been used to quantify the concentration of CO₂ in freshwater. According to basic chemical theory, not considering chemical equilibration of the carbonate system in the sample vials will result in a systematic error. By analysing the potential error for different types of water and experimental conditions we show that the error incurred by headspace analysis of CO₂ is less than 5% for typical samples from boreal systems which have low alkalinity (<900 μmol L⁻¹), with pH (<7.5), and high pCO₂ (>1000 μatm). However, the simple headspace calculation can lead to high error (up to -300%) or even impossibly negative values in highly under saturated samples equilibrated with ambient air, unless the shift in carbonate equilibrium is explicitly considered. The precision of the method can be improved by lowering the headspace ratio and/or the equilibration temperature. We provide a convenient and direct method implemented in a R-script or a JMP add-in to correct CO₂ headspace results using separately measured alkalinity.

1. Introduction

28 The analysis of dissolved CO₂ in water is an important basis for the assessment of the role of surface waters in the global
29 carbon cycle (Raymond et al., 2013). Indirect methods like calculating CO₂ from other alkalinity and pH (Lewis and Wallace,
30 1998; Robbins et al., 2010) are affected by considerable random and systematic errors (Golub et al., 2017) caused e.g. by
31 dissolved organic carbon which may result in significant over estimation of the CO₂ partial pressure (pCO₂) (Abril et al., 2015),
32 or by pH measurement errors (Liu et al., 2020). Thus, direct measurement of CO₂ is highly recommended, particularly in
33 softwaters.

34 Headspace analysis is a standard method to analyse the concentration of dissolved gasses in liquids (Kampbell et al., 1989). In
35 principle, a liquid sample is equilibrated with a gaseous headspace in a closed vessel under defined temperature. The partial
36 pressure of the gas in the headspace is analysed, in most cases either by gas chromatography or infra-red spectroscopy. The
37 concentration of the dissolved gas in solution is then calculated by applying Henry's law after correction for the amount of gas
38 transferred from the solution to the headspace.

39 In freshwater research this is the widely applied standard method to analyse the concentration of the greenhouse gases such as
40 CH₄ and N₂O (UNESCO/IHA, 2010). The method is handy, does not depend on sophisticated equipment in the field, and
41 provides reliable results. Papers and protocols using this method have also been published to analyse dissolved CO₂
42 concentrations in freshwaters (UNESCO/IHA, 2010; Cawley, 2018; Lambert and Fréchette, 2005). However, CO₂ cannot be
43 treated like CH₄ because CO₂ is in dynamic chemical equilibrium with other carbonate species in water while CH₄ is not
44 (Stumm and Morgan, 1981; Sander, 1999). Depending on the CO₂ concentration and pH, reactions of the carbonate equilibrium
45 will either produce or consume some CO₂ in the sample vessel (Cole and Prairie, 2009). Although this is textbook knowledge
46 and has been considered in some recent papers (Golub et al., 2017; Gelbrecht et al., 1998; Rantakari et al., 2015; Aberg and
47 Wallin, 2014; Horn et al., 2017), and is standard practice in marine research (Dickson et al., 2007), a practical evaluation of
48 the systematic error when applying simple headspace analysis to CO₂ on typical freshwaters is missing, presumably because
49 it is widely assumed that "the effect is likely small" (Hope et al., 1995). In this paper, we aim to quantify the error associated
50 with the simple application of Henry's law on headspace CO₂ data, present practical guidelines describing conditions under
51 which the simple headspace analysis of CO₂ can give acceptable results, and offer a convenient tool for the exact CO₂
52 calculation that accounts for the carbonate equilibrium shifts in the sample equilibration vessel. The approach can also be used
53 for correcting previous results obtained by simple headspace analysis of CO₂ using additional information regarding the
54 carbonate system (i.e. alkalinity or DIC), a procedure we tested on a set of field measurements where pCO₂ was determined
55 with independent methods (with and without headspace equilibration). Lastly, we evaluated how likely this correction may be
56 required using a large data set from 337 diverse Canadian lakes.

57 2. Methods

58 2.1 Theoretical considerations

59 If a water sample is equilibrated with a headspace initially containing a known pCO₂ (zero in case N₂ or other CO₂-free gas is
60 used), some CO₂ is exchanged between water and headspace resulting in an altered dissolved inorganic carbon (DIC)
61 concentration in the water of the sample thereby altering the equilibrium of the carbonate system in the water. Depending on
62 partial pressures of CO₂ in the water relative to the headspace gas prior to equilibration, some CO₂ will either be produced
63 from HCO₃⁻ or converted to HCO₃⁻. The exact amount will depend on temperature, pH, total alkalinity (TA), and the original
64 pCO₂ of the water sample. If a CO₂-free headspace gas was applied, the vessel will finally contain more CO₂ than before
65 equilibration and consequently simply applying Henry's law results in a too high pCO₂ value. If ambient air headspace is
66 applied, the error becomes negative in under-saturated samples and the calculated pCO₂ an underestimate.

67 To calculate this error we implemented an R-script that simulates the above mentioned physical and chemical equilibration for
68 a wide range of hypothetical pCO₂, alkalinity, temperature, and headspace ratio ($HR = V_{\text{gas}} / V_{\text{liquid}}$) values. As output, we then
69 compared the corrected (for the chemical equilibrium shift) and non-corrected pCO₂ values. All simulations were performed
70 at 1 atm total pressure and results expressed as μatm .

71 2.1 Field data

72 As a further validation of our simulations, we used various data sets for which the pCO₂ was determined in multiple ways. We
73 collated 266 observations from 4 reservoirs and 3 streams in Germany, 10 Canadian lakes, and a Malaysian reservoir exhibiting
74 a wide range of TA between 0.03 and 1.9 mmol L⁻¹ and pH between 5.2 and 9.8. Two independent techniques were used to
75 measure water pCO₂ in each sampling site: *in situ* NDIR technique and headspace equilibration technique. First, for the *in situ*
76 NDIR technique, the water was pumped through the lumen side of a membrane contactor (mini module, Membrana, U.S.A.)
77 (Cole and Prairie, 2009) and the gas side was connected to a NDIR analyser (EGM4, PP-Systems, U.S.A. or LGR ultra-portable
78 gas analyser) in a counter-flow recirculating loop. Readings were taken when the mCO₂ [ppm] values of the NDIR analyser
79 became stable (fluctuating ± 3 ppm around the mean) at which point the gas loop is in direct equilibrium with the sampled
80 water. Final pCO₂ of the water was calculated by multiplying the CO₂ mole fraction (mCO₂) by the ambient atmospheric
81 pressure. Second, for the headspace technique, the methodology differed slightly among locations. In the German reservoirs,
82 about 40 mL of water sample were taken in 60 mL syringes and eventually occurring bubbles were pushed out by adjusting
83 the sample volume to 30 mL. Samples were stored at 4° C and analysed within 1 day. In the laboratory, 30 mL of pure N₂ gas
84 was added to the syringes after the samples had reached laboratory temperature and the syringes were shaken for one hour at
85 laboratory temperature. After headspace equilibration, the water was discarded from the syringes and the headspace was
86 manually injected into a gas chromatograph equipped with a flame ionization detector (FID) and a methanizer (GC 6810C,
87 SRI Instruments, U.S.A.). In the Canadian lakes, 20 mL of the water samples were taken in 60 mL syringes and equilibrated
88 with 40 mL volume of atmospheric air by vigorously shaking the syringes for 2 minutes. In the Malaysian reservoir, 600 mL

89 of water samples were taken in 1.2 L of glass bottles and equilibrated with 611.5 mL of atmospheric air in 2016. In consecutive
 90 years, diverse volumes of water samples were taken in 60 mL or 100 mL syringes and equilibrated with diverse volumes of
 91 calibrated air brought from the laboratory. The equilibrated air was immediately transferred to and stored in 12 mL pre-
 92 evacuated exetainer vials (Labco Ltd., UK) and returned to the laboratory where it was injected into a gas chromatograph (GC-
 93 2014, Shimadzu, Kyoto, Japan) equipped with a FID. The original water pCO₂ was then calculated according to the headspace
 94 ratio, temperature, and the measured headspace mCO₂ as follows:

$$95 \quad pCO_{2 \text{ water}} = \frac{(mCO_{2 \text{ After eq}} \times K_{h \text{ Eq}} \times P) + \left\{ \left(\frac{V_{\text{gas}}}{V_{\text{liquid}}} \right) \times \left(\frac{mCO_{2 \text{ After eq}} - mCO_{2 \text{ Before eq}}}{V_m} \right) \right\}}{K_{h \text{ Sample}}} \quad \text{Eq. 1}$$

96 with $mCO_{2 \text{ Before eq}}$ and $mCO_{2 \text{ After eq}}$ are respectively the CO₂ mole fractions in the headspace before and after equilibrium
 97 [ppm], $K_{h \text{ Eq}}$ and $K_{h \text{ Sample}}$ = gas solubility at the equilibration temperature and at the sampling temperature (Henry coefficient
 98 (Sander, 2015) [mol L⁻¹ atm⁻¹], P = pressure [atm], V_{gas} = headspace volume, V_{liquid} = sampled-water volume, and V_m = molar
 99 volume [L mol⁻¹] (UNESCO/IHA, 2010). Results from Eq. 1 are reported as pCO₂ at one atmosphere of barometric pressure
 100 and are corrected for ambient pressure at the time of sampling as described previously.

101 The difference between headspace and NDIR method was divided by the pCO₂ measured by the *in situ* NDIR analysis and
 102 expressed as % error. In addition, temperature and pH of the water were measured *in situ* by a CTD probe (Sea and Sun,
 103 Germany) or a portable pH meter (pH meter 913, Metrohm Ltd, Canada). In samples from Canada and Germany, TA was
 104 analysed by titration with 0.11N HCl. In some systems, a single TA measurement was available for multiple dates and therefore
 105 assumes little temporal variability in the alkalinity of these systems. In the Malaysian samples, TA was derived from dissolved
 106 inorganic carbon (DIC) measurements and pH. Analysis of certified calibration gases showed that the analytical error of both
 107 the NDIR instrument and GC was <0.37% at 1000 ppm. Analysis of 7 replicate samples by our GC-headspace method gave a
 108 standard deviation of 6%. This includes all random errors due to sampling, sample handling and analysis.

109 3. Results and Discussion

110 3.1 Simulations from chemical equilibrium

111 Applying a CO₂-free gas as headspace always results in a positive error (over-estimation of the real pCO₂, Figure 1a). If
 112 ambient air is applied as headspace the error becomes negative in case of under saturated samples (Figure 1b). In general, the
 113 error tends to be lower if ambient air is used for headspace equilibration (Figure 1b) compared to equilibration with CO₂-free
 114 gas (Figure 1a), except in undersaturated conditions. This is because less CO₂ is exchanged between water and headspace
 115 during the equilibration procedure. The error will be below 10% in supersaturated and low alkalinity (<900 μmol L⁻¹) samples
 116 which are typical for boreal regions. However, the error can be higher than 100% if the samples are undersaturated. The
 117 magnitude of the error is predictable from pH. Because of the carbonate equilibrium reactions, high pH is necessarily

118 accompanied by low pCO₂ for a given alkalinity. Consequently, the error is large at high pH while it is below 10 % at pH < 8
119 (headspace gas:liquid ratio of 1:1).

120 Our field dataset is consistent with the theoretical predictions. While the fit between the simple headspace calculation and
121 NDIR values over the whole range of values can be considered adequate overall (Figure 2a, R² = 0.92), it is clear that the
122 deviations can become very large (up to about 300%), particularly at water pCO₂ values <600µatm (Figure 2b). As expected
123 from the simulations, the error in undersaturated samples was positive when using CO₂-free gas as headspace and negative
124 (sometimes impossible negative results) using ambient air (Figure 2b). The error became negligible at pCO₂ above 1000 µatm
125 (Figure 2b). Data scatter was considerable as was observed previously (Johnson et al., 2010), most probably because the
126 analytical error of the applied methods was often in the same range as the absolute difference between both methods.

127 **3.2 Error magnitude depends on the experimental procedure**

128 The maximum error depends on how much CO₂ is exchanged between water and headspace. The more gas is exchanged
129 between water and headspace the higher the error is. Thus, the error increases with decreasing solubility coefficient or HR. In
130 high alkalinity samples, the error can be significantly reduced by using a smaller headspace to water ratio (Figure 3). By
131 lowering the headspace ratio from 1 to 0.2 at 20°C the error can be reduced from about 50% to about 10%.

132 Since solubility of CO₂ depends on temperature, the equilibration temperature also affects headspace equilibration. Due to
133 lower solubility at higher temperature, more gas evades into the headspace and thus, the error increases with increasing
134 temperature (Figure 3a,b). At a HR of 1, the error increases from 97 % at 20°C to 111 % at 25°C in a high (1 mmol L⁻¹)
135 alkalinity sample. Thus, the error can be significantly reduced by lowering the equilibration temperature. A possible way to
136 take advantage of this is to perform headspace equilibration at *in situ* temperature in the field, as has been done in several
137 studies. If *in situ* water temperature is lower than typical laboratory temperature, the error is thereby reduced. However, care
138 must be taken to make sure that the exact equilibration temperature is known. For example, an error of 1°C in the equilibration
139 temperature results in a 2 % different pCO₂ value (TA=1 mmol L⁻¹, pCO₂ = 1000 µatm, HR = 1) (Figure A1a). Both ambient
140 air and N₂ can be used as headspace gas. Using N₂, however, eliminates the error associated with the exact quantification of
141 pCO_{2 Before}. Using the same example, an unlikely error of 100 ppm in the headspace gas (mCO_{2 Before eq}) results in a 6.4%
142 different pCO₂ result (Figure A1b).

143 **3.3 What about kinetics?**

144 CO₂ reactivity with water would not cause a problem for headspace analysis if the reaction kinetics were slow compared to
145 physical headspace equilibration. The slowest reaction of the carbonate system is the hydration of CO₂ which has a first order
146 rate constant of 0.037 s⁻¹ (Soli and Byrne, 2002) so that chemical equilibration of CO₂ in water is in the range of seconds
147 (Zeebe and Wolf-Gladrow, 2001; Schulz et al., 2006). This means that chemical equilibrium reactions are faster than physical
148 headspace equilibration and the chemical system can be assumed always to be in equilibrium. Thus, the reactions of the
149 carbonate system have to be fully considered in headspace analysis of CO₂.

150 **3.4 Correction of CO₂ headspace data**

151 If other information regarding the carbonate system of the sample is known (alkalinity or DIC), one can correct for the bias
 152 induced by simple headspace calculations. A procedure to correct headspace CO₂ data using pH and alkalinity is already
 153 available in the SOP N°4 in Dickson et al. (2007) for marine samples and could be adapted to freshwater samples as well. For
 154 convenience, we provide here a modified procedure when the alkalinity of the sample is known by introducing an analytical
 155 solution to the equilibrium problem (iterative in SOP N°4) and by using dissociation constants that may be more appropriate
 156 to freshwaters. The procedure essentially involves estimating the exact pH of the equilibrium solution before and after
 157 equilibration. If the alkalinity of the sample is known, the pH (-log₁₀[H⁺]) of the aqueous solution after equilibration can be
 158 obtained by finding the roots of the 3rd order polynomial

160
$$0 = [H^+]^3 + TA \cdot [H^+]^2 - ([CO_2]K_1 + K_w)[H^+] - 2K_1K_2[CO_2]$$
 Eq. 2

161 where $[CO_2] = pCO_2 \cdot K_{h \text{ Eq}}$ and from which one can obtain the ionisation fraction for CO₂ (α_{CO_2}) as

162
$$\alpha_{CO_2} = \frac{1}{1 + \frac{K_1}{[H^+]} + \frac{K_1K_2}{[H^+]^2}}$$
 Eq. 3

163 where K₁ and K₂ are the temperature -dependent equilibrium constants for the dissociation reactions for bicarbonates and
 164 carbonates, respectively (Millero, 1979), and for estuarine conditions, Millero (2010) as amended in Orr et al. (2015). K_w is
 165 the dissociation constant of water into H⁺ and OH⁻ (Dickson and Riley, 1979). The total DIC contained in the original sample
 166 (DIC_{orig}) can then be calculated as

167
$$DIC_{orig} = \frac{CO_2}{\alpha_{CO_2}} + (CO_{2 \text{ HS}_{after}} - CO_{2 \text{ HS}_{bef}})$$
 Eq. 4

168 where CO₂ is the amount of CO₂ in the equilibrated water [mol], CO_{2HS}_{after + before} the amount of CO₂ in the headspace after
 169 and before equilibration [mol]. Given the DIC concentration of the original solution from Eq. 4 ($[DIC] = DIC_{orig} / V_{liquid}$), the
 170 pH of this solution prior to equilibration can be obtained by finding the roots of the 4th order polynomial

171
 172
$$0 = [H^+]^4 + (TA + K_1) \cdot [H^+]^3 + (TA \cdot K_1 - K_w + K_1K_2 - [DIC]_{orig}K_1) \cdot [H^+]^2 + (K_1K_2 \cdot TA - K_1K_w - 2[DIC]_{orig}K_1K_2) \cdot [H^+] -$$

 173
$$K_1K_2K_w$$
 Eq. 5

174 to then estimate the corresponding ionization fraction α'_{CO_2} as in Eq. 3 above and calculate the original pCO₂ of the sample
 175 as

176
$$pCO_2 = \frac{\alpha'_{CO_2} [DIC]_{orig}}{K_{h \text{ Sample}}}$$
 Eq. 6

177 where $K_{h \text{ sample}}$ is determined for the water temperature during field sample collection (for simplicity, the equations above
 178 assume a 1 atm pressure). We applied the above correction procedure to our samples where pCO₂ was measured in several
 179 samples using both headspace and in situ NDIR methods together with measured alkalinity data. Figure 4 shows that the
 180 corrected values matched the in situ NDIR values nearly perfectly (r²=0.98) whereas the simple headspace calculations

181 resulted, as expected, in significant underestimation for undersaturated conditions, particularly for samples equilibrated with
182 ambient air.

183 We examined the sensitivity of the correction procedure to the precision of the alkalinity measurements and found that the
184 error associated with alkalinity determination does not severely impact the final pCO₂ estimate when using N₂ as a headspace
185 gas. For example, the error in the corrected pCO₂ values is always below 20% even when the alkalinity is known only to within
186 50% error (Fig. 3c). However, more precise alkalinity values are required when using ambient air as a headspace gas in
187 undersaturated conditions (Fig. 3d).

188 Lastly, our simulations (Figs. 2 and 4) provide a complete analysis of the effects of the environmental and methodological
189 conditions on the error incurred when using the simple headspace technique for estimating pCO₂. However, they do not assess
190 how often such problematic conditions occur in inland water systems. To address this question, we used data from 377 lakes
191 for which we had complete ancillary data and precise headspace measurements of CO₂ (<5% error between duplicates)
192 obtained from the pan-Canadian Lake Pulse sampling program (Figure B1a, see Huot et al. (2019) for details). These results
193 show a significant deviation between corrected and uncorrected values, particularly in lakes with high alkalinity (>900 μmol
194 L⁻¹, Figure B1b) and ignoring the correction would have resulted errors >20% in about 47% of the data. Furthermore, our
195 analysis illustrates how a larger headspace ratio significantly exacerbates the magnitude of the error (Figure B1b).

196 The correction calculations have been implemented in an R script and, for a user-friendly interface, as an JMP add-in (or JSL
197 script) (<https://github.com/icra/headspace>). Roots of the polynomials (Eqs. 2 and 5) can be solved using either standard
198 analytical formulas (e.g. Zwillinger (2018)) or by iterative algorithms. Analytical solutions are faster than iterative algorithms
199 but can suffer small numerical instabilities (SD ≈ 1 ppm) in extreme situations (alkalinity >4000 μmol L⁻¹ and pCO₂ < 100 ppm)
200 due to limitations inherent to double precision numerical calculations. The provided scripts consider the barometric pressure
201 and thus, allow calculation of pCO₂ as well as CO₂ concentration [μmol L⁻¹] for *in situ* conditions.

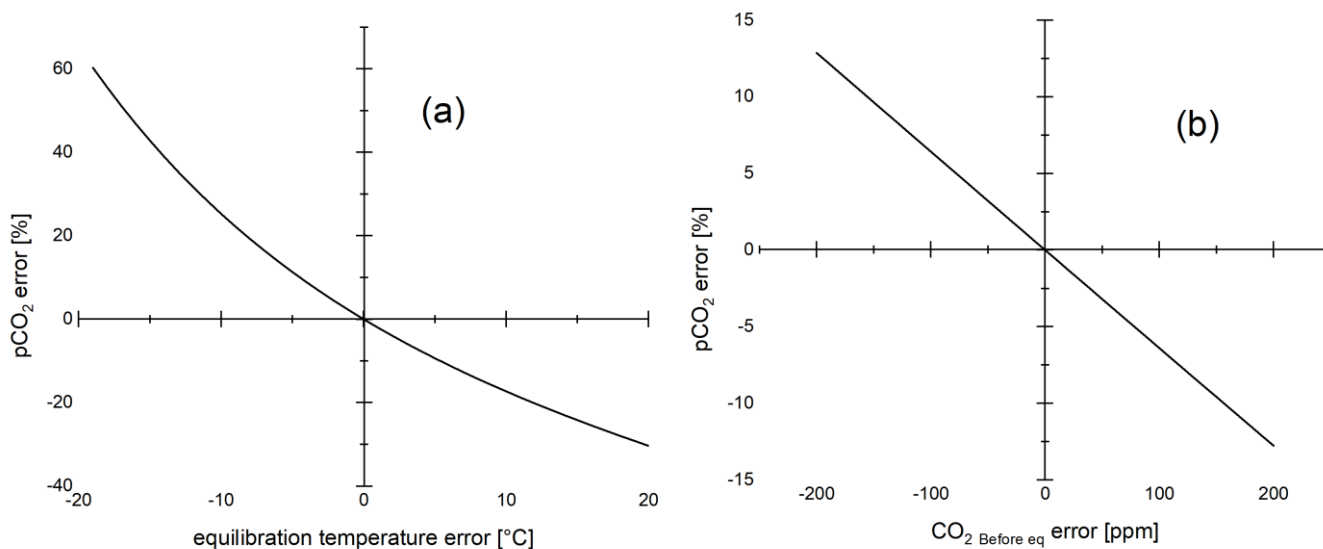

202 **4. Conclusions**

203 The headspace method has been used in several studies about CO₂ fluxes from surface waters. Our error analysis shows that
204 the usual headspace method can be used (error < 5%) if the pH is below 7.5 or pCO₂ is above 1000 μatm (TA < 900 μmol L⁻¹,
205 air headspace), a typical situation in most boreal systems. However, the standard headspace method introduces large errors
206 and cannot be used reliably for under saturated samples, which are typical of eutrophic or low DOC systems. In all other cases,
207 not accounting for the chemical equilibrium shift leads to a systematic over estimation. The magnitude of the error can be
208 reduced by increasing the water/headspace ratio or lowering the equilibration temperature. The magnitude of that error can be
209 roughly estimated from Figure 1. If alkalinity is known, pCO₂ obtained from headspace equilibration can be corrected by the
210 provided scripts. We therefore recommend to always measure alkalinity if the headspace method is to be used for pCO₂
211 determinations. The procedure can also be used to correct historical pCO₂ data. Our field data showed that the correction works
212 well even in highly undersaturated conditions and is not very sensitive to the precise determination of alkalinity if N₂ is used

213 as a headspace gas. The precision of the corrected pCO₂ is similar to that obtained from direct pCO₂ measurement using a field
214 NDIR analyser coupled to an on-line equilibrator (Cole and Prairie, 2009; Yoon et al., 2016).
