

## Supplement on RC

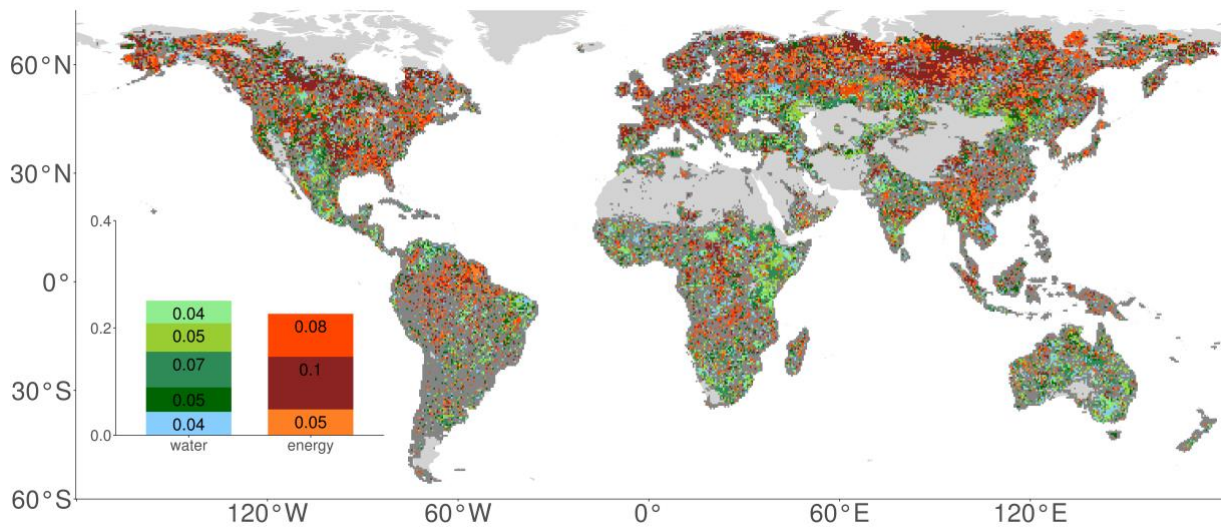

Figure 1\*: Hydrometeorological controls (ERA5 land) of different climate regimes on VHI from NOAA (Kogan et al., 1995). Grid cells are grouped by their long-term temperature and aridity (unit-adjusted net radiation/precipitation). The variable which is important for most of the grid cells for vegetation productivity maxima (a) and minima b), inferred using ET, in one climate regime is used to color the box. The second most important variable colors the smaller squares. Their ratio is denoted in the size of the squares.

## Main manuscript figures

### a) Maximum vegetation productivity

### b) Minimum vegetation productivity

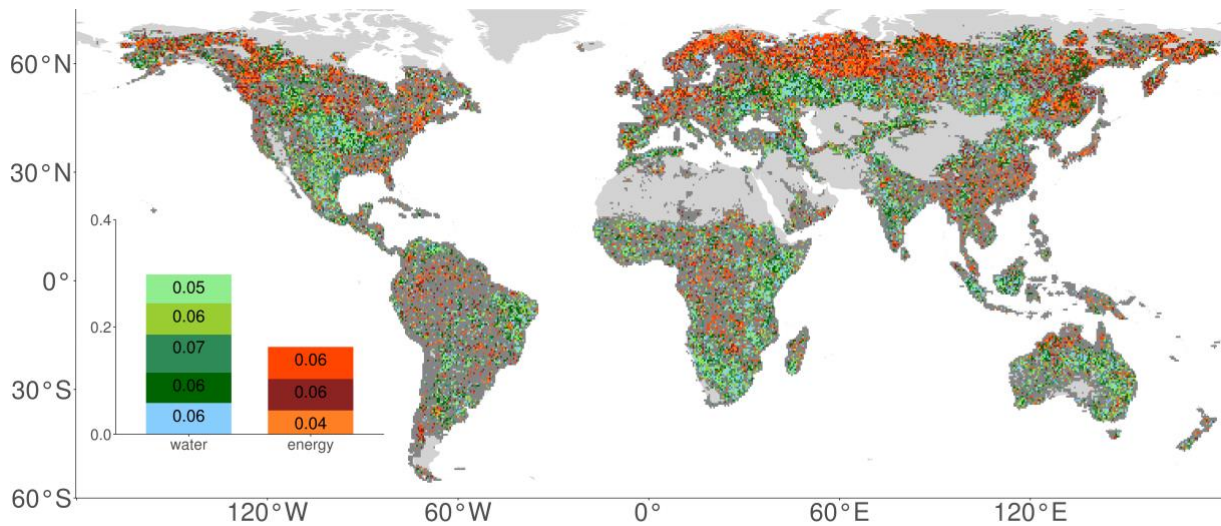

Figure 4. Global distribution of hydrometeorological controls of Sun-Induced Fluorescence (SIF) (a) maxima and (b) minima in respective colors, as assessed from strongest correlations. The inset bar plot indicates the area controlled by each variable relative to the total study area. Dark grey color denotes the study area, in which correlations are negative/insignificant.

■ Soil moisture layer 1    ■ Soil moisture layer 2    ■ Soil moisture layer 3    ■ Soil moisture layer 4    ■ Precipitation  
■ Radiation    ■ Temperature    ■ Vapor pressure deficit    ■ Neg./insign. cor.    ■ Insufficient data

■ Cold spell    ■ Heat wave    ■ Drought    ■ Wet spell    ■ No hazard  
■ Cold spell + drought    ■ Cold spell + wet spell    ■ Heat wave + drought    ■ Heat wave + wet spell    ■ Insufficient data

Importance 2/Importance 1    ■ < 80%    ■ 80% - 90%    ■ > 90%

Figure 5. Hydrometeorological controls of vegetation productivity extremes summarized across climate regimes, (a) and (b) for Sun-Induced Fluorescence (SIF) extremes, (c) and (d) for Enhanced Vegetation Index (EVI) extremes. (e) and (f) display the hydrometeorological hazards co-occurring with the SIF extremes. Box color denotes the main controlling hydrometeorological variable, the second most important variable is indicated in the smaller squares' color, while its size represents the ratio between highest/second highest amounts of grid cells.

### Supplementary material figures

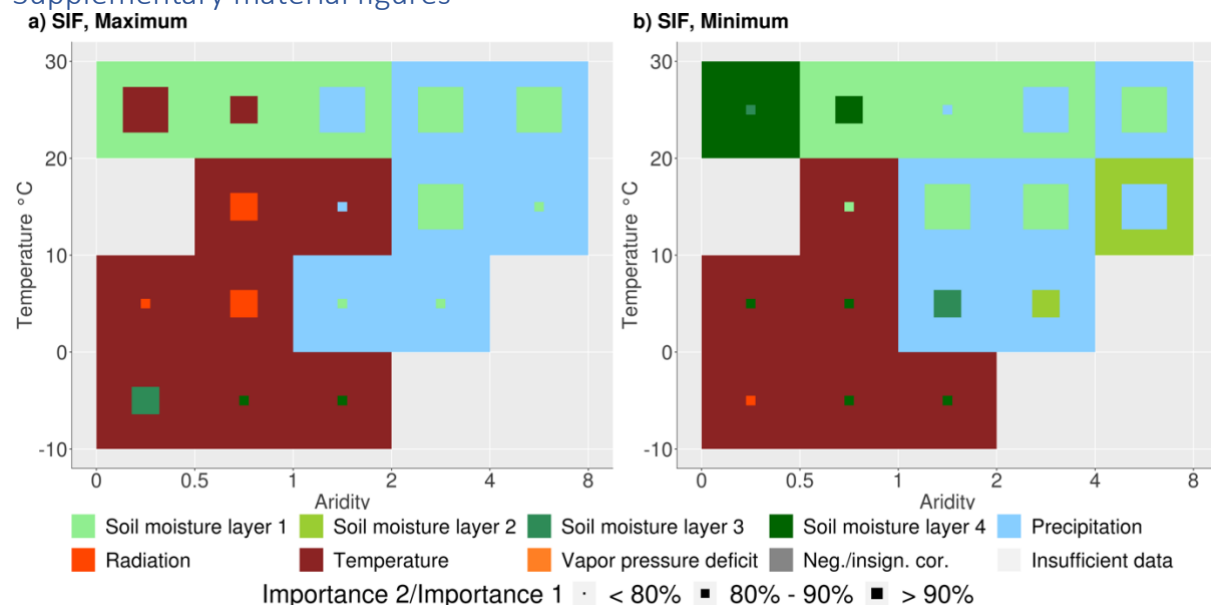

Fig. S4. Hydrometeorological controls (ERA5 land) of different climate regimes with a lag time of 1 month. Grid cells are grouped by their long-term temperature and aridity (unit-adjusted net radiation/precipitation). The hydrometeorological variables of the month preceding the SIF extreme have been used in the computation of most important variable. The variable which is important for most of the grid cells for vegetation productivity maxima (a) and minima b), inferred using SIF, in one climate regime is used to color the box. The second most important variable colors the smaller squares. Their ratio is denoted in the size of the squares.

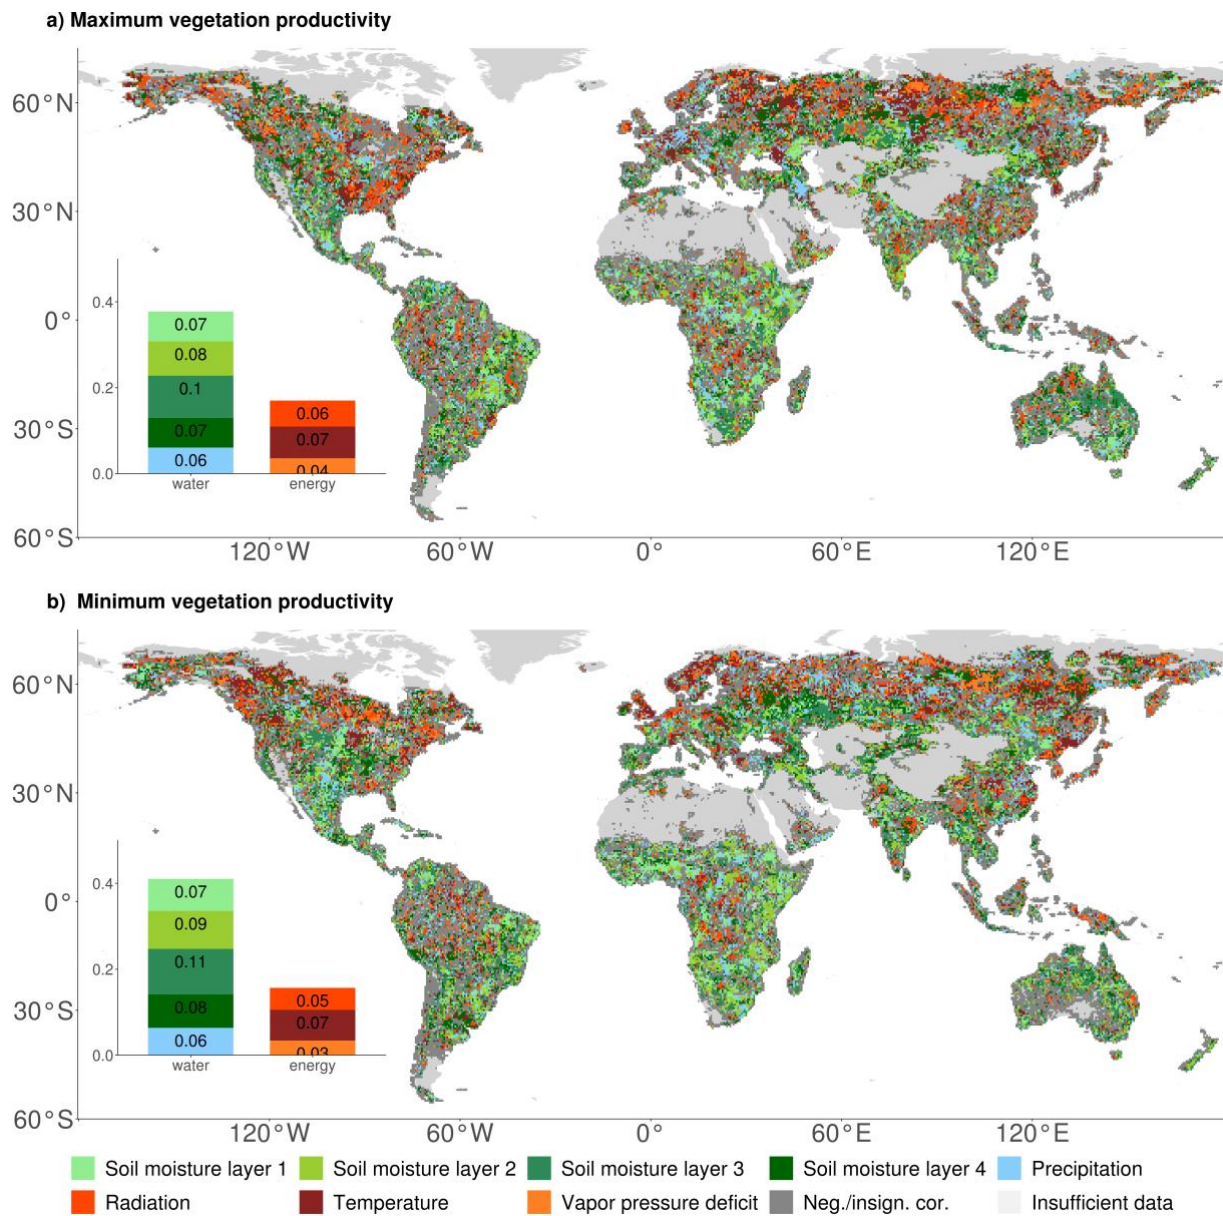

Fig. S5. Global distribution of hydrometeorological controls (ERA5 land) of EVI (a) maxima and (b) minima. The displayed variable correlates strongest with EVI in the extreme months, considering only significant and positive correlations. The bar plot indicates the area controlled by each variable relative to the total study area.

Fig. S6. Hydrometeorological controls (ERA5 land) of different climate regimes on ET from GLEAM. Grid cells are grouped by their long-term temperature and aridity (unit-adjusted net radiation/precipitation). The variable which is important for most of the grid cells for vegetation productivity maxima (a) and minima b), inferred using ET, in one climate regime is used to color the box. The second most important variable colors the smaller squares. Their ratio is denoted in the size of the squares.

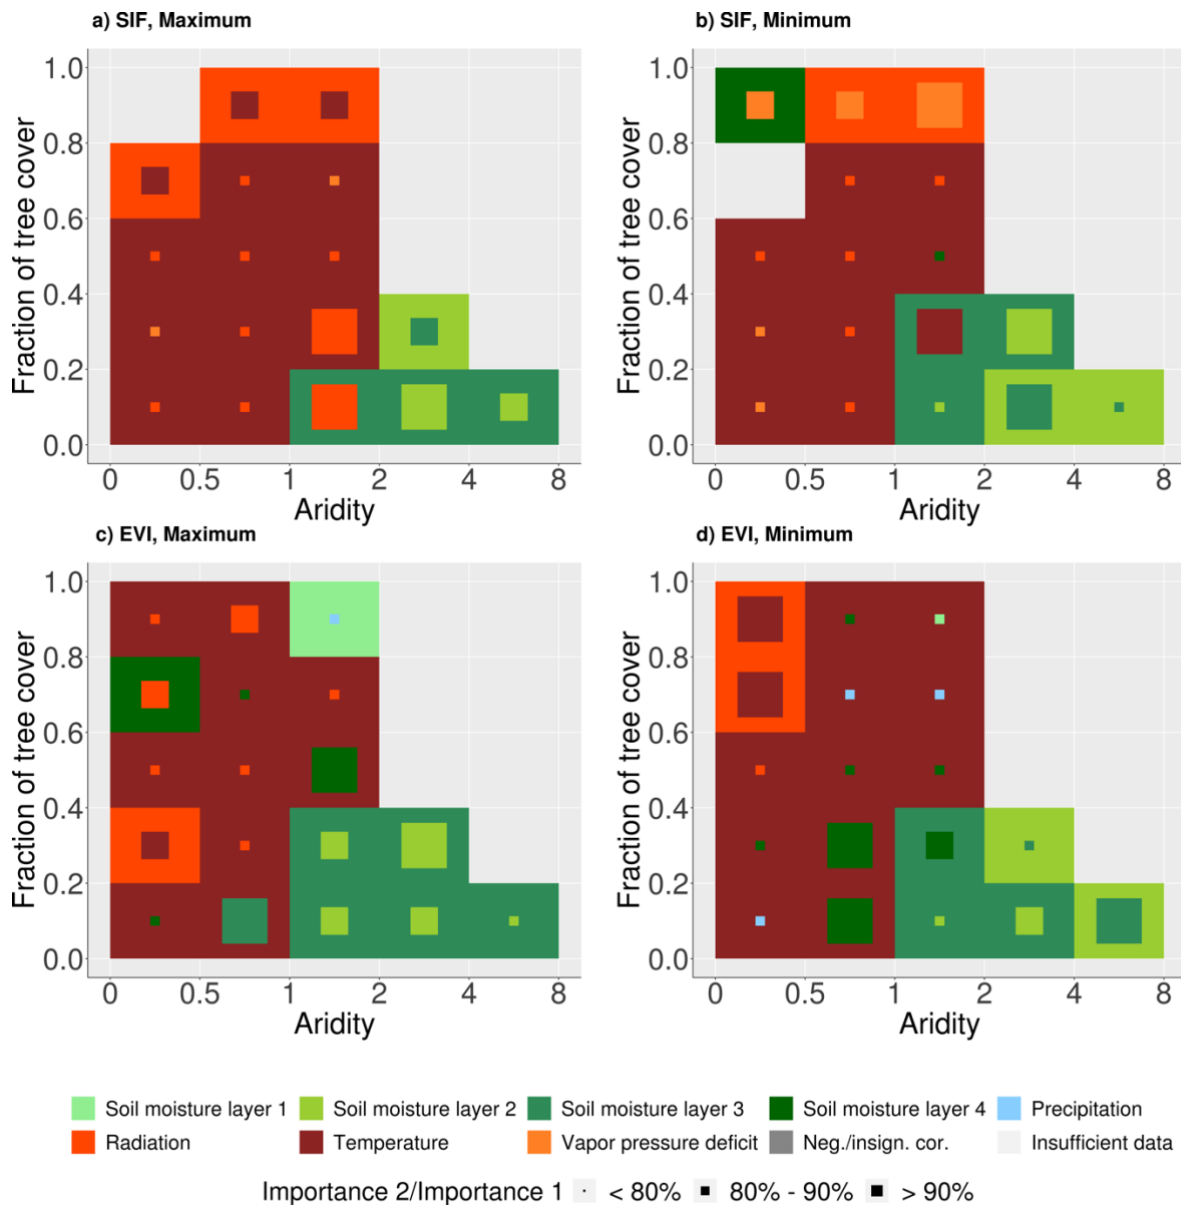

Fig. S7. Hydrometeorological controls (ERA5 land) of different vegetation regimes. Grid cells are grouped by their fraction of tree cover and aridity (unit-adjusted net radiation/precipitation). The variable which is important for most of the grid cells for vegetation productivity extremes (a) and b) SIF; c) and d) EVI) in one vegetation regime is used to color the box. The second most important variable colors the smaller squares. Their ratio is denoted in the size of the squares.
