**Abstract.** ~~Development~~ The development of accurate water quality modeling tools is necessary for integrated water quality management of river systems. ~~The existing~~ Even though some water quality models can simulate dissolved oxygen (DO) concentration ~~quite well accurately~~ during high flow periods and phytoplankton blooms in rivers; ~~however, there are discrepancies during the summer low-flow season that are assumed to be due to the uncertainties related to the organic matter contribution of the model boundary conditions. Therefore, we~~ significant discrepancies remain during low flow periods, when the dilution capacity of the rivers is reduced. We use the C-RIVE biogeochemical model to evaluate the influence of controlling parameters on DO simulations at low flow. ~~Three Sobol~~ Based on a coarse model pre-analysis, three sensitivity analyses (SA) are carried out ~~based on a coarse model pre-analysis whose aim is to develop SA scenarios providing a reduction in the number of model parameters and computation cost as well as hiding inter-parameter interactions using the Sobol method.~~ The parameters studied are related to bacterial community (e.g., bacterial growth rate), organic matter (OM; repartition-partitioning and degradation of OM into constituent fractions), and physical factors (e.g., reoxygenation of the river due to navigation and wind), ~~whose variation ranges are selected based on a detailed literature review.~~ Bacterial growth and mortality rates are found to be by far the two most influential parameters, followed by bacterial growth yield. More refined SA results indicate that the biodegradable fraction of dissolved organic matter (BDOM) and the bacterial growth yield are the most influential parameters under conditions of a high net bacterial growth rate (= growth rate – mortality rate), while bacterial growth yield is independently dominant in low net growth situations. Based on the results of this study, proposals are made for in situ measurement of BDOM under an urban area water quality monitoring network that provides high-frequency data. The results also indicate the need for bacterial community monitoring in order to detect potential bacterial community shifts after transient events such as combined sewer overflows and post-infrastructure improvement in treatment plants. Furthermore, we discuss the integration of BDOM in data assimilation software framework for better estimation of BDOM contribution from boundary conditions, ~~which would result in improved water quality modeling.~~

## 1 Introduction

Dissolved ~~oxygen~~ oxygen (DO) has been considered the most important indicator of water quality in surface water resources (~~Odum, 1956; Escoffier et al., 2018~~) (Streeter and Phelps, 1925; Odum, 1956; Escoffier et al., 2018), because it integrates the

25 biological functioning of a system as well as the impact of anthropogenic forcing. It is the main variable used to evaluate river  
metabolism (Odum, 1956; Staehr et al., 2010; Demars et al., 2015) by comparing the gross primary production (GPP) with  
ecosystem respiration (ER) and defining whether an ecosystem is autotrophic or heterotrophic based on the net ecosystem  
production (NEP = GPP-ER) being positive or negative, respectively (Garnier et al., 2020). Maintaining a sufficient level of  
DO is necessary for the overall health of rivers, not only because of the life dependency of water species (Garvey et al., 2007),  
30 but also for preventing smell and taste degradation (Bailey and Ahmadi, 2014).

The situation of rivers during low flow is of particular interest since studies have demonstrated that the river water quality  
during such flow periods is more vulnerable to degradation due to lower dilution rates. This is particularly the case if the river  
receives organic matter load from ~~wastewater~~ waste water treatment plants (WWTP) and combined ~~sewage~~ sewer overflows  
(CSO), ~~thereby leading~~. These OM loads lead to heterotrophic conditions (Seidl et al., 1998a; Even et al., 2004; Vilmin et al., 2016; Garnier  
35 in the river, where very low DO levels and high fish mortality can be observed (Seidl et al., 1998a; Even et al., 2004; Vilmin et al., 2016; Garnier  
et al., 2020). Therefore, river water quality modeling has been one of the main research interests of water quality managers and researchers  
ever since the use of the very first water quality model (Streeter and Phelps, 1925) to more complex ones (Even et al., 1998; Flipo, 2005; Wang  
et al., 2022), ~~aiming~~ (Billen et al., 1994; Garnier et al., 1995; Even et al., 1998; Vanrolleghem et al., 2001; Flipo, 2005; Wang et al., 2013)  
40 . Its aim is to identify the main determinants of DO evolution and to forecast the response of aquatic systems to human-induced  
pressure, in particular due to ~~releases of wastewater plants~~ waste water treatment plants (WWTPs) outflows.

Large discrepancies exist between DO simulations and observations during low-flow periods ~~and most models are not~~  
~~able to simulate the evolution of DO accurately. In water quality modeling studies at low flow,~~ in water quality models.  
These mismatches were found in the QUESTOR model ~~was~~ applied on the Thames (UK) ~~, which demonstrated discrepancies~~  
~~between observed and simulated DO at low flow (Hutchins et al., 2020) and uncertainties related to benthic respiration were~~  
45 ~~revealed to be the main reason for the mismatch. The Riverstrahler model was applied at low flow (Hutchins et al., 2020),~~  
in the Riverstrahler model applied on the Mosel river (Germany) (Garnier et al., 1999), the Scheldt river (Belgium) (Thieu  
et al., 2009), and the Seine river (France) (Garnier et al., 2020) ~~where discrepancies were noticed between the modeled and~~  
~~observed DO. Yang et al. (2010) used~~. Yang et al. (2010) found the same results in the WASP model ~~to estimate DO in~~  
~~low-flow streams~~ and noted that the uncertainty of the model lies in ~~the difficulty to characterize accurately the~~ characterization  
50 of OM degradation and nitrification rates. ~~The Bailey and Ahmadi (2014) found similar results in the~~ QUAL2E-OTIS water  
quality model ~~shows similar discrepancies, which led Bailey and Ahmadi (2014) to conduct a sensitivity analysis to identify~~  
~~the governing parameters on DO. The ProSe model, which will be used in this study,~~ also has mismatches at low flow  
(Vilmin et al., 2018; Garnier et al., 2020; Wang et al., 2022). Moreover, Cox (2003) compares the existing water quality models  
~~on lowland rivers (flowing slowly with low DO content) and emphasizes that the existing models lack one or more of the~~  
55 ~~required criteria, in particular the inability to account for the expected uncertainties. On the other hand, Wang et al. (2019b, 2022)~~  
(Even et al., 2004, 2007; Vilmin et al., 2018; Garnier et al., 2020; Wang et al., 2022). Among the parameters that control DO  
concentration in water (Cox, 2003), Wang et al. (2022) assume that the uncertainties related to ~~parameterization of (i) the~~  
parameterization of OM degradation kinetics and ~~(ii) repartition of OM input from~~ OM biodegradability at system's boundaries  
(tributary rivers, WWTPs, and CSOs) ~~among dissolved and particulate pools play a~~ play a major role in the discrepancies

60 during non-bloom low-flow periods, without explicitly quantifying their relative influences. However, in this paper, parameters representing OM kinetics and OM repartition are included with the ones of Wang et al. (2018) to quantify their impact on DO variation. observed during low flow periods.

Therefore In order to objectively evaluate the controlling parameters of DO during such periods, a sensitivity analysis (SA) is necessary to study the role of the organic matter contributed by the model boundary conditions on the evolution of DO and river metabolism during low-flow periods via a parameterization of the organic matter repartition into biodegradable fractions and its degradation by bacterial decomposition conducted. Several applications of SA methods can be found for water quality modeling as in Nossent et al. (2011) and for DO and  $NO_3$  modeling as in Bailey and Ahmadi (2014). Wang et al. (2018) summarized a list of (Nossent et al., 2011; Bailey and Ahmadi, 2014; Cho et al., 2017; Wang et al., 2018). Moreover, SA applications in hydrological and water quality modeling and applied SA in contrasting hydrological and trophic contexts, where bacterial parameters were identified as the most influential in a 80-h non-bloom low-flow period. However, the sensitivity of water quality models has not been investigated for long-term (= 45 days to be consistent with the batch test for biodegradable fractions of OM (Servais et al., 1995)) low-flow periods against new parameters accounting for boundary condition uncertainties (OM repartition and degradation) as well as against bacterial and physical parameters are summarized by (Reusser et al., 2011; Wang et al., 2018). In this study, the Sobol method (Sobol, 1993) is chosen in order to understand the inter-parameter interactions.

70 This paper investigates not only the influence of bacterial properties on DO evolution at low flow, but also, for For the first time, the role influence of bacterial properties and that of the quantity and different fractions of OM sources are investigated on DO evolution at low flow using C-RIVE model (Vilmin et al., 2012; Wang et al., 2018). It is conducted for better understanding of the short-term (5 days) and mid-term (45 days) effects of the rapidly and slowly biodegradable OM, respectively. To further understand its functioning, the intra-parameter interactions are considered to evaluate the hiding effect of one parameter on the others. Moreover, a long period simulation (45 days) is conducted that leads to a better understanding of the mid-term effect of slowly biodegradable OM the functioning of the Sobol' SA, the inter-parameter interactions are calculated to address how one parameter hides the influence of other parameters. On the basis of the SA results, suggestions are made for water quality monitoring in urban areas. Finally, proposals are made for a better integration of the influential parameters in data assimilation.

85 Based on the above discussion, the following we address three research questions are proposed to be answered in this study :

1. What are the influential parameters controlling DO during a post-bloom summer low flow period where discrepancies are observed in different water quality models? Is a model that includes bacteria physiological parameters (growth and yield rates) only sufficient to describe DO variation?
2. To what extent is the knowledge of the quantity of OM share, especially that of the biodegradable fraction of dissolved organic matter (BDOM), influential for water quality modeling?
3. What is the hierarchy (importance ranking) among the influential parameters ?

In this article, the sensitivity of C-RIVE (Vilmin et al., 2012; Wang et al., 2018), the biogeochemical module of ProSe-PA (Wang et al., 2019b), is investigated against the background of the aforementioned parameters based on 45- and 5-day DO

simulations. After incorporation of new parameters to account for repartition and degradation of OM, SA is conducted on a synthetic river system mimicking the Seine. Finally, the parameters influencing the evolution of DO and those governing the degradation and repartition of OM are selected. On the basis of the results, proposals are made for a better integration of the influential parameters in data assimilation where the model is coupled with observation data to make an optimal estimate of the temporal evolution of the parameters as well as to produce better simulation results (Cho et al., 2020). Finally, some suggestions are made for water quality monitoring in urban areas in order to fulfill the modeling and monitoring requirements.

## 100 2 Material and methods

This section describes the forward model, the new parameterization and the bibliographically reviewed variation ranges, the SA strategy, and the simulations settings of the study. Since the main goal is to use a SA method to determine the controlling parameters that influence DO evolution during a summer low-flow period, we consider [Here we represent](#) the C-RIVE model (section 2.1) as the forward model of the study and identify the parameters that need to be included in the study. Then, two new sets of parameters are added to the study to account for the uncertainties related to the parameterization of OM degradation kinetics and its [repartition-partitioning](#) into different constituent fractions ([section ??](#)). This is followed by the determination of the variation ranges of the introduced parameters ([section 2.1.2](#)).

Three different SAs are carried out on the basis of a specific SA strategy [Then, the strategy for conducting different SAs is](#) detailed in section 2.3 [based on which 260K–360K simulations are run with the forward model on a case study resembling a](#) non-bloom low flow (section 2.2). Depending on the output of these simulations that are DO time series, the Sobol SA method ([section ??](#)) is implemented to determine the influential parameters. The Sobol indices are calculated up to the second order so as to observe the inter-parameter interactions in addition to their direct and total effects.

### 110 2.1 ProSe-PA

ProSe-PA results from the coupling of the ProSe hydro-biogeochemical model with a particle filter (Wang et al., 2019b, 2022) ~~It was developed to assimilate high-frequency observation data for a better estimation of the model parameters and an improvement in ProSe simulation results. The ProSe model has been developed to simulate the hydro-biogeochemical evolution of the Seine from upstream of Paris until Poses (close to the estuary) and has been applied and validated numerous times (Even et al., 1998, 2007; Flipo et al., 2004, 2007; Polus et al., 2011; Raimonet et al., 2015; Vilmin et al., 2015b, a; Wang et al., 2022) In this model, the river is divided into longitudinal cells of specific length, where three sets of equations corresponding to the three modules of ProSe-PA are solved (hydrodynamics, transport, and biogeochemical). First, the hydrodynamic equations are used to determine the discharge, velocity, and depth at each cell and at each time step, followed by the transport equations for advection, dispersion, and diffusion, and finally the biogeochemical RIVE model equations for the concentrations of all the dissolved and particulate matter.~~

## 2.0.1 C-RIVE Biogeochemical model

### 125 2.1 C-RIVE Biogeochemical model

C-RIVE is a C ANSI library that implements RIVE (Billen et al., 1994) concepts. It is the biogeochemical module of ProSe-PA (Wang et al., 2019b), which concepts (Billen et al., 1994; Garnier et al., 1995). It simulates the cycles of carbon,  $O_2$  oxygen, and other nutrients both in the water and sediment columns of the river. The exchange of dissolved and particulate material between the two layers occurs through diffusion (Boudreau, 1997) and sedimentation-resuspension (due to shear flow and river navigation) (Martin, 2001; Even et al., 2004; Vilmin et al., 2015b), respectively. Numerous applications of RIVE exist for the ProSe and RIVERSTRAHLER softwares (See for instance Garnier et al. (1995, 2005); Even et al. (1998); Flipo et al. (2004, 2007); Thieu et al. (2009)).

RIVE simulates the macro-nutrients cycles (C,N,P, $O_2$ ) based on the physiology of column and sediments of river systems (Fig. 1). The model is community centered and explicitly describes micro-organisms living in water and/or sediments (heterotrophic bacteria, nitrifying bacteria, and phytoplankton), the kinetics of underlying physical-chemical processes, and carbon and nutrient inputs. Model parameters (a hundred to a few hundreds depending on the number of micro-organisms' species simulated) are mostly determined through experiments' communities, such as phytoplankton and heterotrophic bacteria. The physiological parameters of those communities were determined through multiple lab experiments. Both the RIVE model and its parameters were coupled in two river water quality models : RIVERSTRAHLER (Billen et al., 1994) and ProSe (Even et al., 1998). These two models are calibrated and validated on real case applications in different river basins over the world such as in the Danube river (Romania and Bulgaria) (Garnier et al., 2002), in the Day-Nhue river (Vietnam) (Luu et al., 2021), in the Grand Morin river (France) (Flipo et al., 2004, 2007), in the Lule and Kalix rivers (Sweden) (Sferratore et al., 2008), in the Mosel river (Germany) (Garnier et al., 1999), in the Red river system (Vietnam and China) (Quynh et al., 2014), in the Scheldt river (Belgium and Netherlands) (Billen et al., 2005; Thieu et al., 2009), in the Seine river (France) (Even et al., 2004, 2007; Raimonet et al., 2010), in the Somme river (France) (Thieu et al., 2009, 2010), and in the Zenne river (Belgium) (Garnier et al., 2013). Wang et al. (2018) summarized the list of physical, bacterial, and phytoplanktonic parameters related to the carbon cycle with their variation ranges. We examine the equations for DO and OM evolution to understand the role of the different parameters and to select the appropriate parameters for inclusion in the SA.

#### 2.1.1 Dissolved oxygen evolution equations

150 DO in the water column (Fig. 1) depends on physical, bacterial, and phytoplanktonic processes:-

$$\frac{d[O_2]}{dt} = \frac{d[O_2]}{dt}_{\text{physical}} + \frac{d[O_2]}{dt}_{\text{phytoplanktonic}} + \frac{d[O_2]}{dt}_{\text{bacterial}}$$

The physical process depends on reaeration due to dams, wind, navigation, the oxygen holding capacity of water, and the diffusion of oxygen between the water-sediment interface as follows:-

$$\frac{d[O_2]}{dt}_{physical} = \frac{K_{rea}}{h} ([O_2]_{sat}(T) - [O_2]) - \frac{D_s}{h} ([O_2]_{water} - [O_2]_{sed}) + \frac{d[O_2]}{dt}_{dams}$$

- 155 where,  $h$ : water depth  $m$   $[O_2]_{sat}(T)$ : the saturated oxygen concentration at temperature  $T$   $mgO_2/LD_s$ : the coefficient of diffusion between water and sediment layer  $m/s$   $K_{rea}$ : the reoxygenation coefficient calculated from the empirical formula of Thibodeaux et al. (1994) as follows:-

$$K_{rea} = \sqrt{\frac{D_m V_{wat}}{h}} + (K_{wind} V_{wind}^{2.23} (D_m * 10^4)^{2/3} + K_{navig})$$

- 160 where,  $K_{wind}$ : reoxygenation coefficient due to wind  $m/s$   $V_{wind}$ : wind speed  $m/s$   $V_{wat}$ : river flow velocity  $m/s$   $K_{navig}$ : reoxygenation coefficient due to navigation  $m/s$  (Vilmin, 2014)  $D_m$ : molecular diffusivity of DO  $m^2/s$  The phytoplanktonic process depends on phytoplankton respiration ( $R_{O_2,pp}$ ) and photosynthesis ( $P_{O_2,pp}$ ) as follows:-

$$\frac{d[O_2]}{dt}_{phytoplanktonic} = P_{O_2,pp} - R_{O_2,pp}$$

- 165 And the bacterial process that is the main source of oxygen consumption depends on the heterotrophic bacterial kinetics and the availability of substrate matter (S, considered to be the rapidly biodegradable dissolved organic matter,  $DOM_I$ , in this model) as follows:-

$$\frac{d[O_2]}{dt}_{bacterial} = -\tau_{HB} (1 - Y_{HB}) uptake$$

$$uptake = \frac{\mu_{max,HB} e^{\frac{-(T - T_{opt,HB})^2}{\sigma_{HB}^2}} \frac{[S]}{[S] + K_S} [HB]}{Y_{HB}}$$

- 170 where,  $HB$ : the concentration of heterotrophic bacteria (hereafter, called bacteria)  $mgCL^{-1}$   $\tau_{HB}$ :  $1.0 molO_2/molC$  for full oxidation of OM in the respiration process  $Y_{HB}$ : the growth yield of heterotrophic bacteria  $uptake$ : the uptake of substrate (here  $S = DOM_I$ ) for bacteria growth  $mgCL^{-1}h^{-1}$   $T_{opt,HB}$ : optimum temperature for the growth of bacteria  $^{\circ}C$   $\mu_{max,HB}$ : the maximum growth rate of bacteria at  $T_{opt,HB}$   $/h$   $\sigma_{HB}$ : standard deviation of bacteria temperature function  $^{\circ}C$   $K_S$ : Monod half-saturation constant for bacterial growth (uptake constant)  $mgCL^{-1}$

### 2.1.1 Organic matter degradation equations

- 175 The OM in the Seine originates from (i) point releases from WWTP and CSO, (ii) diffuse sources due to soil leaching and surface degradation through tributary rivers, and (iii) mortality of bacteria and phytoplankton (Billen et al., 2001). illustrates

the OM-related process of C-RIVE in the water column where the total organic matter (TOC) is initially divided into dissolved (*DOM*) and particulate (*POM*) forms. *DOM* is composed of three different biodegradable fractions of (i) *DOM*<sub>1</sub> as the limiting substrate (rapidly biodegradable *DOM* in 5 days), (ii) *DOM*<sub>2</sub> (slowly biodegradable *DOM* in 45 days), and (iii) *DOM*<sub>3</sub> (refractory *DOM*). Similarly, *POM* is composed of (i) *POM*<sub>1</sub> (rapidly biodegradable *POM*), (ii) *POM*<sub>2</sub> (slowly biodegradable *POM*) and (iii) *POM*<sub>3</sub> (refractory *POM*). In the C-RIVE model, DO in the water column depends on physical, bacterial, and phytoplanktonic processes (iii) *POM*<sub>3</sub> (refractory *POM*). The benthic processes are not presented in Fig. 1 (Fig. 1). The physical and phytoplanktonic processes tend to provide DO while bacterial processes consume DO. The bacterial respiration, that is the main source of oxygen consumption, depends on the heterotrophic bacterial kinetics and the availability of substrate matter. These equations are accessible in previous publications (Billen et al., 1988; Servais, 1989; Billen, 1991; Wang et al., 2018). For the readability of the paper, they are developed in the supplementary material sections A1 and A2 only.

The degradation of OM happens through the uptake of small monomeric organic substrates (*S*, here *S* = *DOM*<sub>1</sub>) by heterotrophic bacteria on the basis of the HSB model (Billen et al., 1988; Servais, 1989; Billen, 1991) and presented by Eq. and -. These substrates are either the direct input (*P*<sub>S</sub>) of *DOM*<sub>1</sub> from OM sources or produced from the exoenzymatic hydrolysis of the macromolecular fractions of both dissolved (*DOM*<sub>2</sub>) and particulate (*POM*<sub>1</sub>, *POM*<sub>2</sub>) organic matter (Billen, 1991) or they originate from the phytoplankton excretion, which produces more easily utilizable OM (*DOM*<sub>1</sub>) and microorganism lysis products that are macromolecular matter (Fig. 1) (Larsson and Hagstrom, 1979; Garnier and Benest, 1990; Billen, 1991).

$$\frac{d[S = DOM_1]}{dt} = hyd_{DOM_2} + hyd_{POM_{1,2}} - uptake_{HB} + P_S + P_E + P_L$$

where, *P*<sub>S</sub>, *P*<sub>E</sub>, *P*<sub>L</sub>: represent *DOM*<sub>1</sub> from the direct input of OM sources, phytoplankton excretion, and microorganism lysis, respectively  $mgCL^{-1}h^{-1}$  *hyd*<sub>*DOM*<sub>2</sub></sub>: hydrolysis of *DOM*<sub>2</sub> into *DOM*<sub>1</sub> based on the exoenzymatic hydrolysis equation of Michaelis-Menten  $mgCL^{-1}h^{-1}$  *hyd*<sub>*POM*<sub>1,2</sub></sub>: hydrolysis of *POM*<sub>1</sub> and *POM*<sub>2</sub> into *DOM*<sub>1</sub> and *DOM*<sub>2</sub>, respectively, by first-order kinetics  $mgCL^{-1}h^{-1}$

$$hyd_{DOM_2} = k_{hyd,max} \frac{[DOM_2]}{[DOM_2] + K_{DOM_2}} [HB]$$

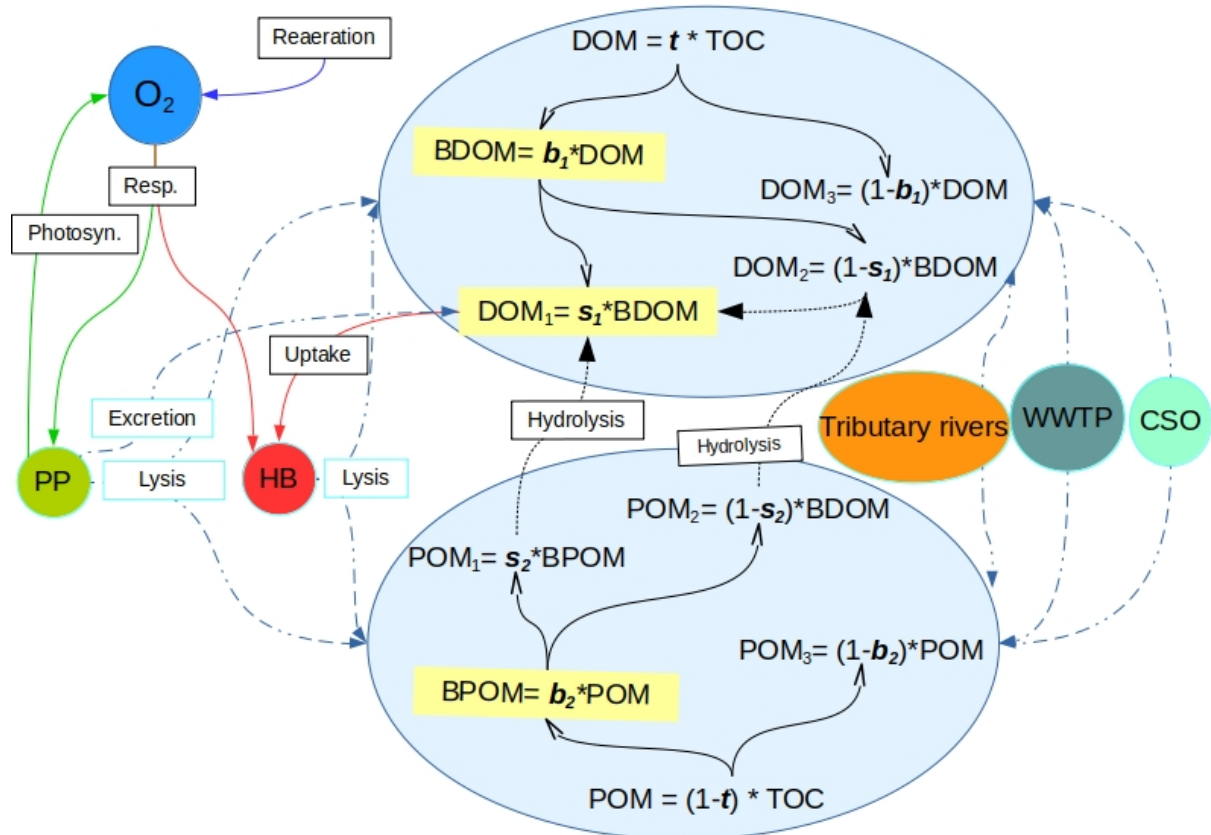

$$uptake_{HB} = \mu_{max,HB} \frac{[DOM_1]}{[DOM_1] + K_s} [HB]$$

where, *uptake*<sub>*HB*</sub>: uptake or consumption of *DOM*<sub>1</sub> by heterotrophic bacteria  $mgCL^{-1}h^{-1}$   $k_{hyd,max}$ : coefficient for hydrolysis of *DOM*<sub>2</sub> into *DOM*<sub>1</sub> / *hK*<sub>*DOM*<sub>2</sub></sub>: constant of semi-saturation for the hydrolysis of *DOM*<sub>2</sub>  $mgCL^{-1}$

## 2.2 Parameterization of organic matter share (repartition) and degradation

In order to account for the uncertainties related to the parameterization of OM degradation kinetics and its repartition into different constituent fractions, the following two sets of parameters are introduced:-

Schematic description of the OM-related process of C-RIVE in the water column. POM: particulate organic matter; DOM: dissolved organic matter; BDOM: biodegradable DOM, BPOM: biodegradable POM (subscripts 1, 2, and 3 refer to rapidly degradable, slowly degradable, and non-biodegradable fractions of OM, respectively); Cyan dashed-dotted lines: OM input from sources and repartitioning between POM and DOM; Solid black lines: repartition of DOM and POM into biodegradability pools; Dotted black lines: Hydrolysis; Remaining solid lines: Biogeochemical processes. Resp.: Respiration; Photo.: Photosynthesis; PP: primary producer; HB: heterotrophic bacteria; WWTP: wastewater treatment plant; CSO: combined sewage overflow

**Figure 1.** Schematic description of the OM-related processes accounted for by C-RIVE in the water column where OM is partitioned into six fractions of dissolved and particulate matter using the five partitioning parameters, namely,  $t$ ,  $b_1$ ,  $s_1$ ,  $b_2$ ,  $s_2$ : POM: particulate organic matter; DOM: dissolved organic matter; BDOM: biodegradable DOM, BPOM: biodegradable POM (subscripts 1, 2, and 3 refer to rapidly degradable, slowly degradable, and non-biodegradable fractions of OM, respectively); Blue dashed-double dotted lines: OM input from sources and partitioning between POM and DOM; Solid black lines: partitioning of DOM and POM into biodegradability pools; Dotted black lines: Hydrolysis; Remaining solid lines: Biogeochemical processes. Resp.: Respiration; Photo.: Photosynthesis; PP: primary producers; HB: heterotrophic bacteria; WWTP: waste water treatment plant; CSO: combined sewer overflow

### 2.1.1 OM-degradation-parameters

205 The parameters related to OM degradation are  $K_s$  (represents uptake of  $DOM_1$  by bacteria),  $K_{DOM_2}$  and  $k_{hyd,max}$  (represent hydrolysis of  $DOM_2$  to  $DOM_1$ ), which have been defined in section ?? and that already exist in C-RIVE. Hydrolysis parameters of POM are not considered in this study because the rate of hydrolysis of  $POM_{1,2}$  is slower than that of  $DOM_2$  by an order of magnitude of 100 to 1000 (Billen et al., 1994).

### 210 2.1.1 OM repartition or share partitioning parameters The OM repartition : from total organic carbon to six OM fractions

The OM partitioning parameters are a novelty added in C-RIVE. Indeed, former version of C-RIVE did not include any parameter to define the repartition partitioning of OM into DOM and POM and then further into their corresponding fractions  $DOM_{1,2,3}$  and  $POM_{1,2,3}$ . ~~The following five parameters are introduced to represent the repartition of OM:-~~

$$t = \frac{DOM}{TOC}$$

215 
$$b_1 = \frac{BDOM}{DOM}$$

$$s_1 = \frac{DOM_1}{BDOM}$$

220 
$$b_2 = \frac{BPOM}{POM}$$

$$s_2 = \frac{POM_1}{BPOM}$$

where, TOC: total organic matter or carbon (= (see Fig. 1 for the definitions). In the recent development of C-RIVE, the total organic carbon (TOC) is initially divided into dissolved ( $DOM_+$ ) and particulate ( $POM$ )  $mgCL^{-1}$   $BDOM$ : biodegradable DOM (=  $DOM_1 + DOM_2$ )  $mgCL^{-1}$   $BPOM$ : biodegradable POM (=  $POM_1 + POM_2$ )  $mgCL^{-1}$  forms by  $t$  : ratio between dissolved and total organic matter parameter (Fig. 1). Then,  $DOM$  is divided into biodegradable (BDOM) and refractory ( $DOM_3$ ) fractions by  $b_1$  : ratio between biodegradable DOM and DOM parameter. Then, thanks to  $s_1$  : ratio between parameter, BDOM is further divided into (i)  $DOM_1$  as the limiting substrate (rapidly biodegradable DOM and biodegradable DOM in 5 days) and (ii)  $DOM_2$  (slowly biodegradable DOM in 45 days).  $POM$  is similarly divided into its constituent

230 fractions using  $b_2$  : ratio between biodegradable POM and POM and  $s_2$  : ratio between rapidly biodegradable POM and biodegradable POM-

parameters. The equations concerning these five parameters and that of OM degradation are accessible in supplementary material section A3. To further clarify,  $DOM_{1,2,3}$  and  $POM_{1,2,3}$  were state variables in the former version of C-RIVE. They used to be forced information provided by user. They are now defined by the proposed repartition model which has

235 the above-mentioned five parameters. The the only required forced information is TOC that comes from experimental data. Therefore, the five OM repartition parameters partitioning parameters ( $t, b_1, b_2, s_1, s_2$ ) give us the possibility to conduct a

sensitivity analysis to quantify their influence on ~~the output of C-RIVE namely~~ DO concentration. ~~Thanks to Given~~ this model, we can ~~have take into account for boundary conditions, per say river inflows,~~ varying  $DOM_{1,2,3}$  and  $POM_{1,2,3}$  ~~depending fractions that depend~~ on the values of the five parameters ~~in a specific rivert,~~  $b_1$ ,  $s_1$ ,  $b_2$  and  $s_2$ .

240 ~~figure~~ OM repartition into the six fractions of dissolved and particulate matter in terms of the five repartition parameters, namely,  $t$ ,  $b_1$ ,  $s_1$ ,  $b_2$ ,  $s_2$  figure

## 2.1.2 Parameters for SA and ~~bibliographical review of~~ their variation ranges

~~Following the parameterization, the~~ The influence of 17 parameters ~~as listed in on oxygen concentrations~~ are evaluated in the SA. ~~This includes this study (Tab. 1). Various types of parameters are identified:~~ two physical parameters that account for  $O_2$  re-aeration; seven bacterial parameters that account for bacteria growth, mortality, and respiration; three OM degradation parameters ~~that demonstrate OM kinetics;~~ and five OM ~~share parameters that represent the repartition of TOC into smaller dissolved and particulate fractions~~ partitioning parameters (Fig. 1).

Before proceeding to a SA, it is necessary to specify the range of variation of ~~these parameters according to the existing literature. As indicated in,~~ the each parameter according to a *a priori* distribution based on former knowledge. ~~Those distributions~~ are assumed to be uniform within a range, whose definition relies on a literature review. The range of variation of the ~~repartition partitioning~~ and degradation parameters (Tab. 1) is selected based on a detailed bibliographical review, ~~which is discussed and tabulated thoroughly in Hasanyar et al. (2020, 2021);~~ while the variation of physical and bacterial parameters is retrieved from ~~Wang et al. (2018)~~ (Hasanyar et al., 2020, 2021; Wang et al., 2018). Table 1 also includes the range of variation of TOC, which represents the total organic matter input in the model due to the boundary conditions and varies from 1 to 10  $\text{mgCL}^{-1}$  ~~mgC~~ under low flow ~~(also retrieved from Hasanyar et al. (2020)).~~ However, phytoplanktonic parameters are not included in this study because they exert an influence only during algal bloom periods (Wang et al., 2018), whereas this study is conducted under non-bloom situations where heterotrophic activity is dominant (Hasanyar et al., 2020).

\* The upper limit identified by Wang et al. (2018) is decreased from 0.13/h to 0.07/h in order to avoid complete DO depletion in simulations longer than 5 days

## 2.2 Case study

The synthetic case developed by Wang et al. (2018) is adapted for the application of SA methods SAs on C-RIVE parameters during a low-flow period (Fig. 2). It is a river stretch with a width of 100 m and a length of 1000 m representing the Seine river. The low-flow period is identified-characterized with a discharge of  $80 \text{ m}^3/\text{s}$  based on the data at Bougival station during the summer season  $\text{m}^3 \text{ s}^{-1}$ . The simulation period is set at 45 days day-long in order to be coherent with the experimental protocol of the BDOM measurement (Servais et al., 1995) where it is considered as the threshold between the biodegradable and refractory fractions of TOC in a batch experiment. On the other hand, that considers 45 days as a limit between refractory and slowly biodegradable organic matter. Moreover, a 45-day simulation period is also necessary for studying the long-term effect of TOC degradation on river metabolism.

**Figure 2.** Synthetic scheme representing a reach of the Seine river. (modified from Wang et al. (2018)).

Considering the discharge and the wet section, the numerical experiment can be viewed as a lagrangian one, where we follow a river body along a river network of the above mentioned dimension with a speed of  $0.14 \text{ m s}^{-1}$ .

### 2.2.1 Initial conditions

A non-bloom low-flow situation (large heterotrophic bacteria biomass presence in the river) is considered to represent the low-flow period. Table 2 lists the initial concentrations for both water and sediment compartments that are set based on the mean concentrations of the simulations at Bougival station during the 2007-2012 period (Vilmin et al., 2016) except for water temperature (depending on summer season), DO (depending on oxygen solubility), POM and DOM fractions (depending on the TOC concentration and share partitioning parameters), and phytoplankton and bacterial biomass (depending on a post-bloom condition). Indeed, the sum of  $DOM_{1,2,3}$  As far as organic matter is concerned, TOC is first defined and then distributed into its DOM and  $POM_{1,2,3}$  is equal to the desired TOC, but they are distributed among the six fractions based

on the five OM share-POM fractions depending on the values of the five OM partitioning parameters ( $t$ ,  $b_1$ ,  $s_1$ ,  $b_2$ ,  $s_2$ ). The hyporheic exchanges (between groundwater and river) are ignored in this work because the contribution of groundwater to downstream rivers is well known to be a downstream river (Strahler order > 6), such as the Seine river at the crossing of the Paris urban area, is negligible with respect to the discharge of large rivers (Strahler order > 6) the river itself. For the Seine river the groundwater contribution along a 100 km is around  $1 \text{ m}^3 \text{ s}^{-1}$  with respect to the Seine discharge amounting for  $80 \text{ m}^3 \text{ s}^{-1}$  during severe low flow conditions (Pryet et al., 2015).

### 2.3 Sensitivity analysis strategy

The objective is to identify different scenarios under which the SA has to be conducted in order to detect the influential parameters under a summer low-flow condition. Therefore Before defining in detail the SA, a coarse pre-analysis consisting in forward simulations of the C-RIVE model is first conducted with extreme values of a small number of representative parameters conducted with extreme parameter values. Then, the necessary scenarios various SA are developed to assess the assumptions and conclusions put in place in the pre-analysis.

#### 2.3.1 Pre-analysis of the model under parameter with extreme limits parameter values

First, we need to select certain parameters for the pre-analysis. We consider  $\mu_{max,hb}$ ,  $mort_{hb}$  and  $Y_{hb}$  as they were found to be influential in the study of Wang et al. (2018) under non-bloom situations. However, to decrease the number of parameters,  $mort_{hb}$  and  $\mu_{max,hb}$  are represented together as a single parameter called "net growth (NG)."

$$Net\ Growth\ (NG) = \mu_{max,hb} - mort_{hb}$$

Fixing  $mort_{hb} = 0.02 \text{ /hh}^{-1}$  at its reference value and  $\mu_{max,hb}$  ranging between  $0.022 \text{ h}^{-1}$  and  $0.07 \text{ /h}$ , net growth was found to range  $\text{h}^{-1}$ , the net growth ranges from  $0.002 \text{ h}^{-1}$  to  $0.05 \text{ /hh}^{-1}$  while the range for  $Y_{hb}$  is taken from Table 1. On the other hand, as the OM share-As the OM partitioning parameters are not C-RIVE inputs, we consider BDOM to represent them in the model. Its range is calculated in given by Eq. (1)-(2) in order to be statistically independent based on the TOC repartition diagram (Fig. ??) as follows:

$$BDOM_{min} = TOC_{ref} * t_{ref} * b_{1,min} \quad (1)$$

300

$$BDOM_{max} = TOC_{ref} * t_{ref} * b_{1,max} \quad (2)$$

Here,  $TOC_{ref}$  is a reference TOC value and fixed at  $5 \text{ mgCLmgC L}^{-1}$  (considered as the baseline concentration of TOC in the Seine river (Vilmin et al., 2016)), the reference  $t$  ( $t_{ref}$ ) = 0.7 is the average value of  $t$  variation range and  $b_1$  is taken from Table 1. This way BDOM varies following  $b_1$  only and therefore remains statistically independent from the other parameters.

**Table 2.** Initial concentrations of the simulations

No	Species	$C_{ini,water}$	$C_{ini,sediment}$	Unit
1	$NH_4$	0.12	0.33	[mgN $\mu L^{-1}$ ]

305 Eight simulations pertaining to eight different combinations of the minimum and maximum values of the net growth, its associated yield and BDOM are launched (Table 3) and accordingly for each combination, the evolution of DO,  $DOM_1$ ,  $DOM_2$ , and BDOM is plotted (Fig. 3).

~~Therefore, eight simulations pertaining to eight different combinations of the minimum and maximum values of these three parameters are conducted (–) and accordingly for each combination, the evolution of DO,  $DOM_1$ ,  $DOM_2$ , and BDOM is~~

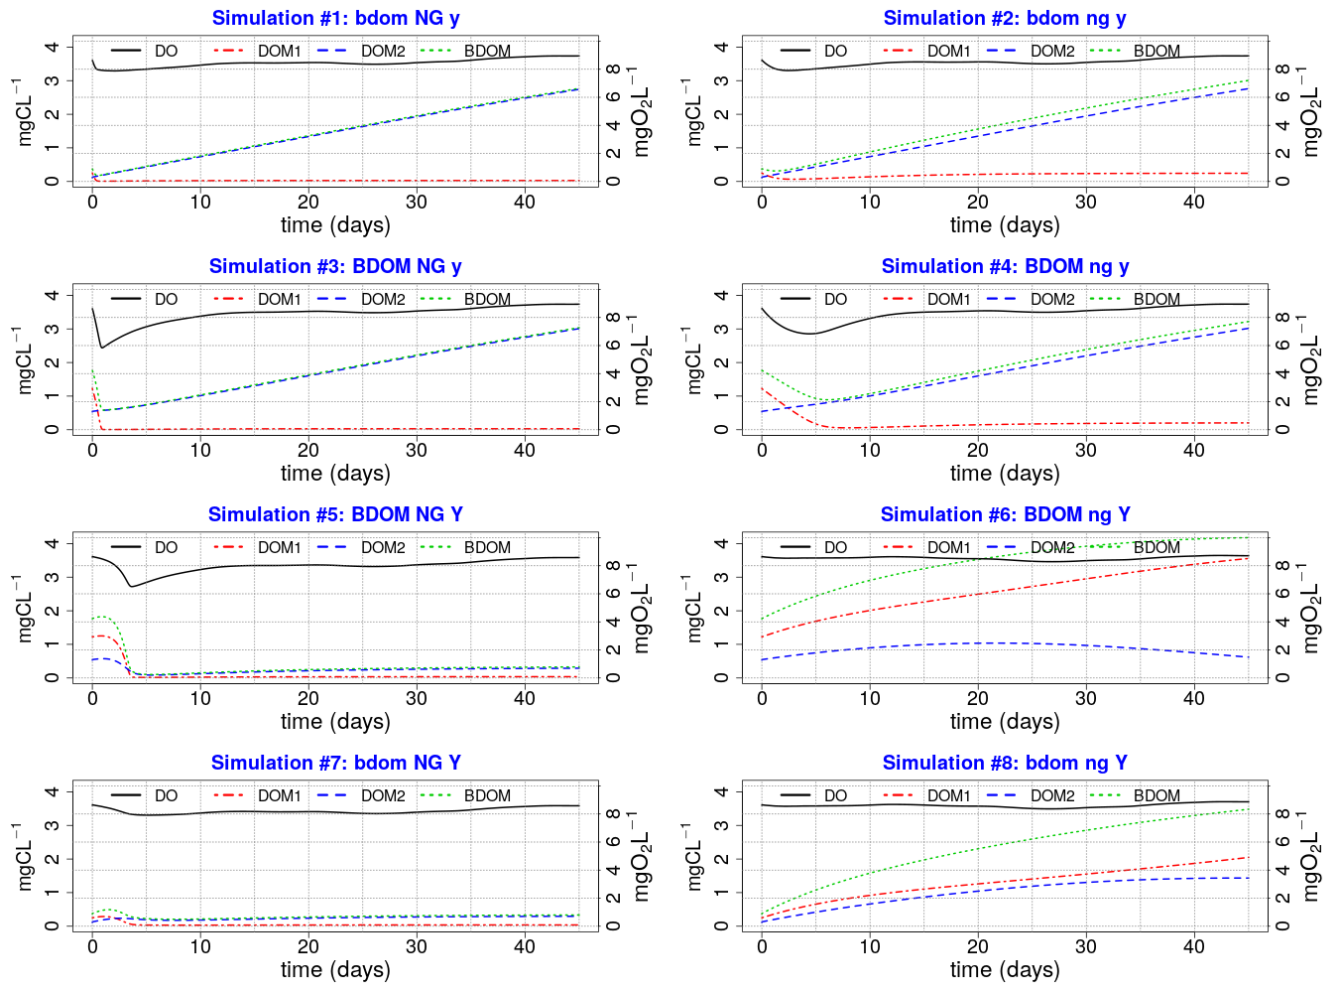

**Table 3.** Combinations Definition of the three parameter values for eight single simulations achieved with extreme values of biodegradable dissolved organic matter, net growth of bacteria community and its associated yield

Sim. No.	BDOM	Net growth	$Y_{hb}$
1	0.35	0.05	0.03
2	0.35	0.002	0.03
3	1.75	0.05	0.03
4	1.75	0.002	0.03
5	1.75	0.05	0.5
6	1.75	0.002	0.5
7	0.35	0.05	0.5
8	0.35	0.002	0.5

310 plotted (Fig. 3). In order to discriminate easily among the eight plots of single simulations using their titles, any parameter name written in capital or small letters means that its maximum or minimum value is used, respectively in that particular simulation. For example, plot 3 (BDOM NG y), that corresponds to simulation 3 in , is a simulation where the maximum values of BDOM and net growth and the minimum value of  $Y_{hb}$  are used.

As can be observed in Fig. 3, From the pre-analysis, we hypothesize that:

- 315 1. The net growth is one of the most influential parameters on DO because all simulations on the left side with a high net growth demonstrate significant depletion of DO than those on the right side having low net growth rates.
- 320 2. DO is sensitive to BDOM under high net growth conditions. This could be observed by comparing simulations 3 (BDOM NG y), and 4 (BDOM ng y), 5 (BDOM NG Y) under high net growth condition) with simulations 4 and 6 (BDOM ng Y) have high BDOM where all except simulation 6 demonstrate considerable DO depletion. This shows the importance of BDOM in the depletion of DO. The reason for lack of depletion in 6 could be attributed to the combination of under
- 325 3. DO is not sensitive to BDOM under low net growth and a high yield due to which BDOM is not consumed. However, comparing rates. Comparison of simulations 6 (BDOM ng Y) and 7 (bdom NG Y), we observe demonstrate that even a lower high BDOM coupled with high low net growth (simulation 7) has more 6) has less effect on DO than a high BDOM coupled with low net growth (simulation 6). This shows the interaction effect of BDOM with net growth parameters and the fact that despite BDOM being the primary requirement for depletion of DO, the net growth needs to be high in order to demonstrate the influence of BDOM and provide the means for its consumption which would result in DO depletion. Moreover, the difference between two horizontally adjacent simulations is in the net growth, which is maximum for the left-hand simulations and minimum for those on the right and as a result, all simulations on the left side with a low

**Figure 3.** Eight plots of single simulations; (XX yy ZZ) Any parameter name written in capital or small letters means that its maximum or minimum value is used, respectively, in that specific single simulation. For example, plot #3 (BDOM NG y) that corresponds to simulation #3 in Table 3 is a simulation where the maximum values of BDOM and net growth and the minimum value of  $Y_{hb}$  are used

330 BDOM coupled with high net growth demonstrate more depletion or consumption of DO than those on the right side.  
 This shows the influence of net growth parameters ( $\mu_{max, hb}$ ,  $mort_{hb}$ ) on the model at low flow. (simulation 7) .

### 2.3.2 Sensitivity analysis scenario development Understanding river metabolism controls with multiple sensitivity analyses

335 Having performed the pre-analysis, we understood the importance of BDOM and that of the net growth parameters such that BDOM is needed primarily in order to be consumed so that DO could be depleted. And then we discern that BDOM consumption is high when net growth is at its highest value. Therefore, the following three different sensitivity analysis

~~scenarios whose parameters are detailed~~ Three sensitivity analyses (SAs) are derived to test the former three hypotheses.  
The detail of each SA parameterization is available in Table 4 ~~need to be conducted~~.

The first SA is conducted by assuming the general influence of net growth parameters in the pre-analysis, and in order to  
340 have a broader view of the model sensitivity with respect to all the model parameters. Based on the pre-analysis, we observed  
that the main effect due to BDOM is linked to high net growth rates, therefore, we can assume that the effect of parameters  
other than net growth parameters is demonstrated when they are coupled with a high net growth condition. In addition, since a  
significant interaction (the difference between the first and total sensitivity indices) is observed between net growth parameters  
in Wang et al. (2018), they are assumed to be hiding the influence of other parameters. ~~Therefore, in order to confirm these~~  
345 ~~two assumptions and to observe the influence of other parameters, we~~ We therefore implement a second SA where net growth  
parameters are fixed at its highest value. This SA removes the possibility of ~~interaction~~ interactions among net growth and other  
model parameters. It results in a better evaluation of the model sensitivity with respect to the parameters whose influences might  
be hidden by the dominant and interacting parameters.

The third SA is performed to verify the second SA assumption that parameters other than net growth exert their influence  
350 only under a high net growth condition, and thus the same parameters could be deemed non-influential under a low net growth  
situation. ~~therefore the~~ The net growth parameter is fixed at its lowest value. ~~The~~

To summarize, the settings for the three SAs are as follows:

1. **First SA (All parameters included):** There are 17 defined parameters (Table 1 & Table 4) in the model, the simulation  
period is **45 days**. It is repeated for each TOC concentration from 1 to 10 ~~times for every TOC concentration of 1-10~~  
355 ~~mgCL<sup>-1</sup>mgC L<sup>-1</sup>, with a 1 mgC L<sup>-1</sup> increase step.~~
2. **Second SA (Fixed high net growth):** The ~~net growth parameters are fixed as follows:-~~

*Fixed high net growth = High bact. growth rate ( $\mu_{max, hb} = 0.07/h$ ) – Bact. mortality rate ( $mort_{hb} = 0.02/h$ )*

influence of twelve parameters is evaluated (Table 4). The bacteria net growth rate is fixed to its maximum value using  
the highest value of the bacteria growth rate ( $\mu_{max, hb} = 0.07 \text{ h}^{-1}$ ) and a mortality rate of  $0.02 \text{ h}^{-1}$ . Furthermore, to  
360 decrease the computational cost of the model, the three OM ~~share partitioning~~ parameters ( $t$ ,  $b_1$  and  $b_2$ ) from the first SA  
are narrowed to BDOM and BPOM whose variation ranges are calculated based on the following Eq. (3)-(6) ~~as follows:~~

$$BDOM_{min} = TOC * t_{ref} * b_{1,min} \quad (3)$$

$$BDOM_{max} = TOC * t_{ref} * b_{1,max} \quad (4)$$

365

$$BPOM_{min} = TOC * (1 - t_{ref}) * b_{2,min} \quad (5)$$

$$BPOM_{max} = TOC * (1 - t_{ref}) * b_{2,max} \quad (6)$$

Here TOC varies between 1-10, therefore, similar to the first SA, this SA is repeated

370 ~~Where,  $t_{ref}$  is set to 0.7. TOC varies between 1 and 10 times corresponding to each TOC case. The  $\text{mgC L}^{-1}$ , with a  $1 \text{ mgC L}^{-1}$  increase step. The time length is set to 5 days accordingly to the pre-analysis also, which demonstrated that BDOM or precisely the substrate ( $DOM_1$ ) is was consumed in less than 5 days under the high net growth condition (simulations 1, 3, 5 & 7), therefore imposing a 5 days simulation period. Twelve parameters are evaluated under this scenario (-).~~

375 3. **Third SA (Fixed low net growth):** ~~The influence of twelve parameters is evaluated (Table 4).~~ This SA is conducted in a similar way ~~to than~~ the second SA except that this time  $\mu_{max,hb}$  is fixed at a lower value of  $0.022 \text{ h}^{-1}$  in order to simulate a very low net growth rate condition ~~as follows:-~~

~~*Fixed low net growth = Low bact. growth rate ( $\mu_{max,hb} = 0.022/h$ ) – Bact. mortality rate ( $mort_{hb} = 0.02/h$ )*~~

380 ~~Similar to the second SA, this of approximately  $0.002 \text{ h}^{-1}$ . This SA is also repeated 10 times and implemented under implemented for a 5-day simulation period. Twelve parameters are also evaluated under this scenario (-) period of time and repeated 10 times to simulate TOC ranging from 1 to  $10 \text{ mgC L}^{-1}$ .~~

## 2.4 Sensitivity analysis methodology

Each of the three aforementioned SAs is implemented based on an innovative SA methodology initially proposed in Wang et al. (2018) and adopted in this study, where the influence of input parameters (X) is evaluated on the C-RIVE model according to  
385 the variations of a large set of DO simulations (model output, Y). The ~~followings steps are pursued in this approach:-~~

~~**Input parameter identification:** Initially, a set of D input parameters (-) are identified with their corresponding ranges of variation (-). **Parameter sampling and model input creation:** Saltelli's extension of the Sobol sequence (Saltelli, 2002) implemented in PYTHON SALIB package (Herman and Usher, 2017) is employed to create different combinations of the input parameters, which are designed to produce optimized simulations and efficient analysis results. Considering a sample  
390 size of 10,000 (N) (needed for stable results based on Nossent et al. (2011)), a matrix with a size of  $N(2D+2) \times D$  is created for each SA scenario where every row represents one set of input parameters for the model.~~

~~**Model simulation:** In this step, the model inputs are launched into C-RIVE for the simulation period considered with a 1-min time step. As an output, a DO time series matrix with a size of  $N(2D+2) \times M$ , where M is the number of output time steps based on a 15-min output time step<sup>1</sup>, is created corresponding to each input matrix created in the previous step.~~

<sup>1</sup> $M = 45 \text{ or } 5 \text{ day simulation period} \times 24 \text{ hrs} \times 3600 \text{ min} / (1 \text{ min simulation time step} \times 15 \text{ min output time step}) = 4230 \text{ or } 480$  depending on the simulation period, respectively

mgCL<sup>-1</sup> is used in this study to represent the TOC range of 1-10 mgCL<sup>-1</sup> and to show the results in case they are similar across  
all TOC concentrations)-

figurehEnsemble of the 260,000 DO simulations for TOC = 5 mgCL<sup>-1</sup> in the second SA scenario figure

400 **Dimensionality reduction:** The empirical orthogonal function (EOF) method is an adaptation of principal component  
analysis (PCA) to study a phenomenon that changes with a continuous variable, such as time, and is applied to transform  
the output data from one coordinate system into another by introducing new uncorrelated (orthogonal) variables (principal  
components) (Jolliffe and Cadima, 2016). EOF is adopted to transform the model output, which is a DO times series matrix  
composed of M columns into a smaller matrix where each simulation can be represented by a linear combination of EOFs. The  
coefficients of this linear combination are indeed orthogonal projections that maximize the variance while transforming the data  
405 from a higher-dimensional space into a lower one. The way EOF decreases dimensionality is such that it ranks the components  
based on the maximized variance. In other words, most of the information is kept in the first few components, thereby making  
it possible to reduce the number of dimensions without losing a considerable amount of information (Wold et al., 1987). In

410 this study, the first  $k$  EOF elements that constitute at least 99% of the total model variance are considered to represent each single simulation of the DO time series as shown for TOC = 5 mgCL<sup>-1</sup> in the second SA (Fig. ??a), where four ( $k$ ) significant EOFs are found such that the first EOF ( $EOF_1$ ) represents almost 55% of the total variance. b illustrates the evolution of the eigenvalues of the four ( $k$ ) EOFs with time, which are consequently used to represent each simulation in terms of the  $k$  new coordinates. Thereby, an  $N(2D+2) \times M$  matrix is converted into a new matrix of  $N(2D+2) \times k$ , which will be subjected to the Sobol SA method. The R *precomp* function is used to conduct the EOF analysis. figureha) Cumulative sum of EOF variances and b) time evolution of four ( $k$ ) significant EOFs for TOC = 5 mgCL<sup>-1</sup> in second SA figure

415 **Sobol sensitivity analysis:** The Sobol SA method (Sobol, 1993; Saltelli et al., 2010) is applied in this study to evaluate the sensitivity of the model output against the input parameters. It is a variance-based method that classifies the parameters based on their contribution to and/or influence on the total variance of the model output (Brookes et al., 2015). It is a convenient method to be used for SA of complex models that involve interactions between parameters. In this method, the model output ( $Y$ ) is expressed as a function of  $D$  parameters:-

420 
$$Y = f(X) = f(X_1, \dots, X_D),$$

such that the model output could be decomposed by elementary functions:-

$$f(X) = f_0 + \sum_{i=1}^D f_i(X_i) + \sum_{i=1}^{D-1} \sum_{j=i+1}^D f_{ij}(X_i, X_j) + \dots + f_{1,\dots,D}(X_1, \dots, X_D)$$

---

Here  $f_0$  is the expectation of the model output and each one of the elementary functions have a zero mean and can be computed by integration:-

425 
$$f_0 = \int_{[0,1]^D} f(X) dX$$

---

$$f_i(X_i) = -f_0 + \int_{[0,1]^{D-1}} f(X) dX_{\sim i}$$

---

$$f_{ij}(X_i, X_j) = -f_0 - f_i(X_i) - f_j(X_j) + \int_{[0,1]^{D-2}} f(X) dX_{\sim (ij)}$$

---

430 On the other hand, the total unconditional model variance could be defined as:-

$$V(Y) = \int_{[0,1]^D} f^2(X) dX - f_0^2$$

---

Thereby, the total unconditional variance of the model can be expressed as:-

$$V(Y) = \sum_{i=1}^D V_i(X_i) + \sum_{i=1}^{D-1} \sum_{j=i+1}^D V_{ij}(X_i, X_j) + \dots + V_{1,\dots,D}(X_1, \dots, X_D)$$

---

where,  $V_i$  is the partial-variance of the  $i_{th}$  parameter and  $V_{ij}$  is the interaction effect of the  $i_{th}$  and  $j_{th}$  parameters. The partial variance is calculated as:-

$$V_{i_1, \dots, i_s} = \int_0^1 \dots \int_0^1 f_{i_1, \dots, i_s}^2(X_{i_1}, \dots, X_{i_s}) dX_{i_1}, \dots, dX_{i_s}$$

where  $s = 1, \dots, D$  and  $f_i$  is an elementary function. Therefore, the first-order Sobol SA indices can be computed as follows:-

$$S_i = \frac{V_i}{V}$$

$S_i$  is also called as the "main effect" because it represents the contribution of a single input parameter  $i$  on the total-variance. The total sensitivity index ( $S_{Ti}$ ), also called "global effect," is another index that represents the sum of the first-order index ( $S_i$ ) and the effect of the interaction between the parameters and is calculated as follows:-

$$S_{Ti} = S_i + \sum_{j \neq i} S_{ij} + \dots$$

here,  $S_{ij} = \frac{V_{ij}}{V}$  is called the "second-order index" and measures the interaction between a pair of parameters  $X_i$  and  $X_j$ . Therefore, the sum of second-order interactions of any parameter  $X_A$  with other parameters ( $X_B, \dots, X_D$ ) is considered to represent the second-order index of each parameter ( $S_2$ ) as follows:-

$$S_{2,A} = \sum_j S_{Aj}$$

Since the output of previous step is a matrix of  $k$  vectors corresponding to the  $k$  EOFs, the Sobol indices of parameters are initially calculated  $k$  times for each EOF and then added while being weighted by the variance of the corresponding EOF. [necessary steps pursued for SA are summarized in supplementary material section B.](#)

The total computation time from step 1 to 5 [Each SA](#) is 12 h for each TOC case of the first SA, after using a parallel code in PYTHON and dividing the simulations in several groups to decrease the computational cost using 20 processors [\(performed with a Python script that computes on an Intel\(R\) Xeon\(R\) E5-2640 and frequency of 2.40\(20 cores @ 2.4 GHz\).](#) The computation time is 3 h for each TOC case of [computational time is 12h per TOC value for the first SA, while it is reduced to only 3h per TOC value for](#) the second and third SA, which clearly demonstrates the gain in time compared with the first SA. [ones.](#)

### 3 Results

This section presents the results of the three Sobol SAs during a summer low-flow period. The influential parameters of each analysis are discussed in the following paragraphs.

### 3.1 First SA: All parameters

**Figure 4.** Sobol SA results of **first SA: All parameters** (a) Sobol SA results for TOC = 5 mgCL<sup>-1</sup>; (b) Evolution of the normalized total sensitivity indices of the influential parameters with TOC

460 Figure 4a presents the results of the Sobol SA method ~~on for~~ TOC = 5 mgCL<sup>-1</sup>. It is expressed by a bar plot of the total sensitivity ( $S_T$ ), first-order sensitivity ( $S_1$ ), and second-order sensitivity ( $S_2$ ) indices of the parameters. The higher-order sensitivity indices are also calculated in terms of the difference between the total and the first- and second-order indices ( $S_T - S_1 - S_2$ ). The parameters are ranked based on their  $S_T$  and the most influential parameters are shown by the shaded area, which includes parameters constituting 95% of the total variance of the model output. ~~However, this As the first SA is conducted on~~  
 465 ~~different TOC values of 1-10 for TOC values ranging from 1 to 10 mgCL<sup>-1</sup>, and therefore in order to summarize all of the results together which corresponds to ten runs. For each run,~~ the evolution of the normalized total sensitivity indices ( $S_T^*$ ) of the six most influential parameters ~~with TOC is presented in is plotted~~ (Fig. 4b).

~~figurehSobol SA results of first SA: All parameters (a) Sobol SA results for TOC = 5 mgCL<sup>-1</sup>; (b) Evolution of the normalized total sensitivity indices of the influential parameters with TOC figure~~

470 ~~figurehResults of (a) Second SA: Fixed high net growth; (b) Third SA: Fixed low net growth figure~~

~~According to Fig. 4b, the three bacterial parameters of DO is controlled by the bacterial mortality rate ( $mort_{hb}$ ), maximum bacterial growth rate ( $\mu_{max,hb}$ ), and bacterial yield ( $Y_{hb}$ ) exert the most influence on DO evolution, and, whatever the TOC concentration, they represent the majority of the model sensitivity (Fig. 4b). By increasing TOC, we observe a gradual decrease~~

in the influence of  $mort_{hb}$ , but an increase in the influence of  $Y_{hb}$ . This result obtained over the 45-day simulation period (Fig. 4) confirms the assumption made in the pre-analysis step (sec 2.3.1) regarding the overall dominance of bacterial parameters in long-term low-flow periods.

Apart from the constant of navigation ( $K_{navig}$ ), which is a physical parameter, the other two influential parameters ( $K_s$ ,  $b_1$ ) are OM-related parameters that were introduced in this study.  $K_s$  seems to be more important in lower TOC concentrations compared to  $b_1$  whose influence increases in higher TOC concentrations.

On the other hand, these results ~~These results also~~ confirm the assumptions made in the pre-analysis step that the dominant parameters tend to hide the influence of other parameters. Observing the second-order ( $S_2$ ) and higher-order sensitivity ( $S_T$ - $S_1$ - $S_2$ ) indices of  $mort_{hb}$ ,  $\mu_{max,hb}$  and  $Y_{hb}$  in Fig. 4a, very strong interactions can be highlighted between these parameters, i.e., a significant portion of their total sensitivity indices is due to their internal interactions. ~~On the other hand,~~  $b_1$  and  $K_s$  ~~also exert an influence due to their~~ exert their influence only through higher-order ~~interaction~~ interactions with these three parameters. ~~Thus, in order to see what happens behind net growth parameters, and in order to observe the dominant parameters under two extreme conditions of high and low net growth rates, the second and third SAs are conducted by fixing the  $mort_{hb}$ ,  $\mu_{max,hb}$  parameters under the notion of net growth rate.~~

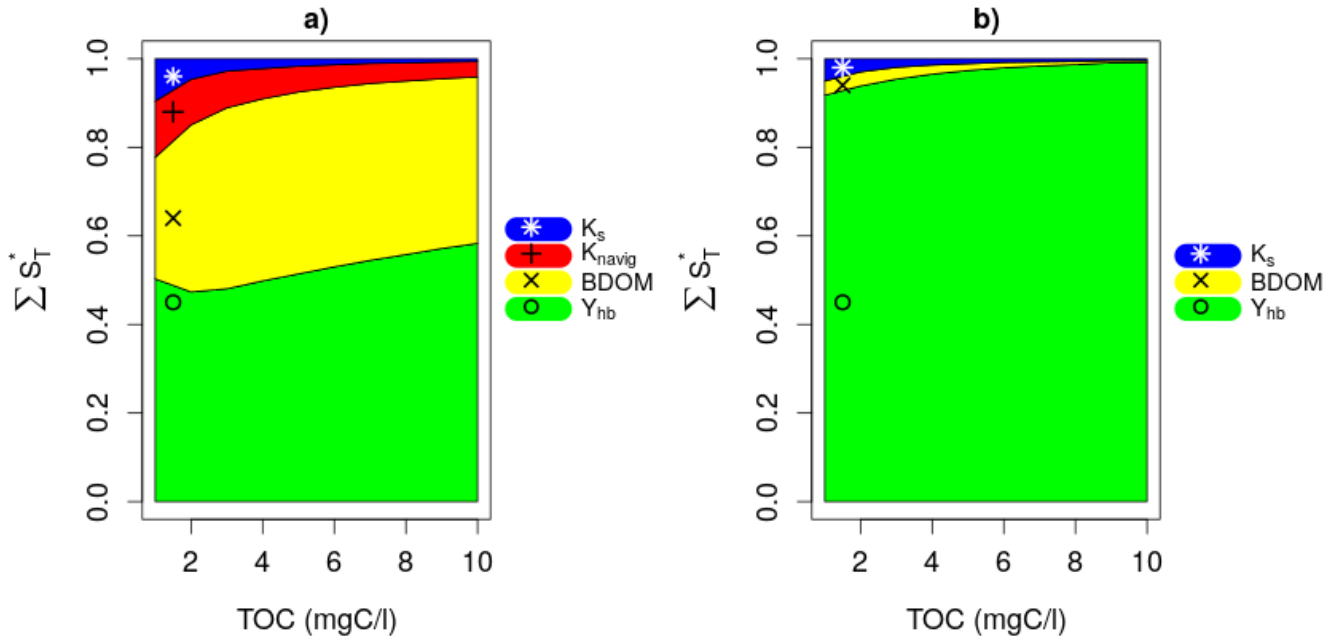

~~Moreover~~In the first SA, the three OM parameters ( $t$ ,  $s_1$  and  $s_2$ ) are found to be non-influential, which means they can be excluded from SA by fixation in the second and third SA while calculating the variation ranges of BDOM and BPOM (Eq. (1)-(4)). Finally, the inclusion of  $b_1$  among influential parameters out of the five OM parameters ~~confirms~~ validates the selection of the BDOM concentration instead of other OM components in the pre-analysis step.

### 3.2 Second SA : ~~Fixed under high bacteria net growth rate~~

~~Based on Fig. 5a which depicts the results of the second SA, it is shown that~~ The bacteria yield,  $Y_{hb}$ , and BDOM are the most influential parameters under high net growth rate conditions (Fig. 5a). This is due to the fact that the bacterial community manages to consume most of BDOM under a high net growth condition and then at some point, BDOM becomes a limiting factor for their growth. This result confirms the assumption made in the pre-analysis that the influence of parameters other than net growth parameters will be displayed if they are studied under a high net growth condition. The other important parameters are  $K_{navig}$  and  $K_s$  whose influence is reduced by ~~increased~~ increase in TOC. Moreover, very small interactions are observed between the parameters because almost all of their global influence stem from their main effects ( $S_T \approx S_1$  for each parameter), which once again confirms the previous consideration that interactions are related to the effect of a varying net growth rate.

### 3.3 Third SA : ~~Fixed under low bacteria net growth rate~~

The results of the third SA (Fig. 5b) reveal that  $Y_{hb}$  ~~is a predominantly~~ only is the influential parameter under a low net growth rate condition across ~~all~~ whatever the TOC concentrations. This is due to the fact that, with such a low net growth rate, the bacterial community hardly grows at all and ~~therefore BDOM is~~ BDOM is subsequently not a limiting factor for ~~bacterial growth as there is not enough bacterial activity under a low net growth rate condition~~ such a small bacterial growth.

**Figure 5.** Results of (a) Second SA: Fixed high net growth; (b) Third SA: Fixed low net growth

This result ~~verifies~~ confirms the assumption made in the second SA by displaying all previous influential parameters except  $Y_{hb}$  as non-influential.

~~In observing the role of BDOM, we conclude that by increasing the net growth rate, Finally, the second and third SA show that~~ the influence of BDOM increases. Here, we need to highlight that the actual upper limit of net growth is 0.11/h (Wang et al., 2018) compared to the current value of 0.05/h because the upper limit of  $\mu_{max,hb}$  is reduced in in order to prevent complete DO depletion of simulations that occur due to the combination of extreme values in Sobol sampling. Therefore, it can be envisaged that BDOM may have a greater influence under the actual range of on DO increases with an increasing bacteria net growth rate.

## 4 Discussion

515 In this section, we ~~highlight answers to the proposed research questions and~~ propose first synthesize of our results, before  
analyzing the limitations in terms of physical processes accounted for. We then discuss what consequences do our results have  
on water quality monitoring in urban areas and on data assimilation.

### 4.1 Hierarchy of the most influential parameters on DO during low flow period

This study confirms that over a 45-day post-bloom summer low-flow period and whatever the TOC concentration, the bacterial  
520 net growth rate ~~represented by  $m_{ort,hb}$ ,  $\mu_{max,hb}$~~  and  $Y_{hb}$  control the DO evolution. This is in ~~accordance~~ agreement with the  
findings of the study by Wang et al. (2018), which was conducted over a 4-day simulation period. However, the mentioned  
bacteria physiological parameters are not sufficient to describe DO variation because the OM ~~repartition~~ partitioning parameter,  
 $b_1$ , and the OM degradation parameter,  $K_s$ , are also influential at low flow under a high bacteria net growth rate.

Conducting the Sobol' SA for 5-days under a high bacterial net growth rate condition demonstrated the significant influence  
525 of BDOM and  $Y_{hb}$  at low flow. This is in connection with the findings of Hullar et al. (2006); Crump et al. (2003) that  
emphasized the importance of BDOM on bacteria population. This result is also in accordance with Bailey and Ahmadi (2014)  
who consider the model boundary condition as influential on DO but they do not specify which portion of the OM neither  
do they conduct their study at low flow. Nevertheless, this work is the first quantitative recognition of the role of BDOM on  
DO evolution that illustrates BDOM as the most influential fraction of the total organic matter entering a river system from its  
530 boundary conditions.

### 4.2 Limitations of the sensitivity analysis

This study is conducted under carbon source conditions where TOC ~~is varied between 1-10 mgC/L~~ varies between 1 and 10  
mgC L<sup>-1</sup>. It is also assumed that a carbon sink condition never happens. Indeed, carbon depletion would preclude the possibility  
to quantify the influence of the carbon on the DO concentration. Therefore the upper limit of  $\mu_{max,hb}$  is reduced from 0.13  
535 ~~Ah<sup>-1</sup>~~ to 0.07 Ah<sup>-1</sup> so as to avoid depletion of both carbon and oxygen during the simulation period.

~~On the other hand~~ Moreover, since C-RIVE currently lacks the radiation effects of bacteria population, this process is not  
considered in this work. Nevertheless, it is recommended to be considered in future researches as radiation is found to damage  
the bacteria DNA impacting their growth and oxygen intake rates (Matallana-Surget and Wattiez, 2013). This phenomenon  
could be included in the model in a simplistic approach either by increasing bacterial mortality or decreasing its growth rate  
540 by a given factor. However, it is necessary to find experimental data in order to ~~find this factor because~~ quantify the effects of  
radiation that also depend on the type of bacterial community (Fernandes et al., 2021).

### 4.3 Consequences of the results on water quality monitoring in urban areas

Rivers are highly sensitive to urban outflows at low flow (Seidl et al., 1998a; Huang et al., 2017) due to their low dilution  
capacity at this period of the year. Moreover, the construction or renewal of sanitary facilities, such as WWTP and CSO during

545 transient events, induce changes in water quality due to changes in DOM, and BDOM concentrations (Servais and Garnier, 1993; Seidl et al., 1998b). As a result, this induces potential shifts in bacterial communities, which have been found to be related to ~~DOC-DOM~~ source and its biodegradability (Hullar et al., 2006; Crump et al., 2003) such that an increase in BDOM is considered to increase the diversity of bacterial populations (Landa et al., 2013). Even et al. (2004) therefore ~~recommend~~ recommended a regular reassessment of the influential bacterial parameters. The sampling frequency in the monitoring stations should be set-up not only considering the temporal variability of the variable of interest, but also integrating possible successions of species.

~~On the one hand, our~~ Our study provides the list of important parameters for water quality modeling at low flow. ~~On the other hand, these parameters are dynamic (varying with time). Thus in urban areas submitted to large WWTP outflows, continuous monitoring networks would be able to provide up-to-date values of parameters that influence the water quality.~~

555 ~~Considering the results of this study which introduce initially several~~ For the bacterial parameters (mortality rate, maximum growth rate and growth yield) ~~as having the most influence on DO evolution~~, we propose the implementation of regular bacterial community sampling campaigns in the framework of the water quality monitoring program. Samples should thus be taken in river waters upstream from the major urban areas, and in the effluents of major WWTPs and CSOs.

~~Then~~ Finally, considering the importance of BDOM at low flow periods, we propose the addition of BDOM measurement in the existing and new monitoring stations. ~~These Innovative methods such as specific ultraviolet absorbance at 254 nm (SUVA<sub>254</sub>) and fluorescence spectroscopy (Parlanti et al., 2000, 2002; Goffin et al., 2017) could be proposed for high frequency measurement of OM and BDOM specifically. The monitoring stations shall be dense and capable of characterizing enough in space so that they could characterize~~ the upstream tributary rivers and the outflow of anthropogenic sources such as WWTP and CSO ~~because an appropriate spatial resolution (Polus et al., 2010).~~ Such a spatial density and consideration of point and non-point pollution sources ~~(Dixon et al., 1999; Do et al., 2012)~~ are necessary to cover all BDOM sources ~~.~~ ~~On the other hand, innovative methods such as specific ultraviolet absorbance at 254 nm (SUVA<sub>254</sub>) and fluorescence spectroscopy (Parlanti et al., 2000, 2002; Goffin et al., 2017) could be proposed for high frequency measurement of OM and BDOM specifically (Dixon et al., 1999; Polus et al., 2010; Do et al., 2012).~~

#### 4.4 Consequences of the results on data assimilation (DA) in water quality modeling

570 ~~Coupling water quality models with data assimilation techniques allows to avoid relying on a continuous water quality monitoring.~~

Data assimilation is a method that combines observation data and physically based modeling in a statistical framework. It consists in sequentially updating the model parameters so that the output of the model will match the observation at each time step (Carrassi et al., 2018). These techniques not only estimate the evolution of influential parameters thanks to observation data such as that of DO, but also provide enhanced simulation results of state variables.

The first assimilation tool that uses the particle filter technique (a statistical technique where numerous simulations are launched instead of one single simulation and are weighted based on-upon how well they reproduce the observed data) to couple with a water quality model is the ProSe-PA software (Wang et al., 2019b; Wang, 2019a; Wang et al., 2022). While

580 studying a dry year using this software, mismatches were found between simulated and observed DO in during low-flow periods (Wang et al., 2022). These mismatches were assumed to be due to insufficient biodegradable organic matter loading in the model caused by underestimated BDOM inputs to the Seine river. Therefore, based on our SA results, we can confirm that hypothesis and propose the incorporation of BDOM (the most influential OM-related parameter through the  $b_1$  parameter) as a new component of ProSe-PA. It will facilitate not only the estimation of BDOM, but also consequently improves the simulation results subsequently.

585 Another consequence of our results is that ~~in accordance with the results of the second and third SA,~~ it would be appropriate to fix one or both of the  $mort_{hb}$  and  $\mu_{max,hb}$  parameters during data assimilation in order to facilitate parameter identification. In addition, the model of OM repartition partitioning (Fig. ??1) shall be explicitly included in the data assimilation software and BDOM from each. The description of BDOM in each major organic matter source (tributary river, WWTP, and CSO) should also be independently represented in the DA scheme ~~due to their distinct~~ because each source brings its own specific contribution of organic matter and heterotrophic bacteria in urban rivers (Garnier et al., 1992; Servais and Garnier, 1993; Seidl et al., 1998b).

~~Finally, we can conclude that once a water quality model capable of data assimilation is validated and its uncertainties are suitably reduced, it can provide acceptable estimates of water quality variables in periods when monitoring is not possible or at locations where accessibility is an issue (Reis et al., 2015; Jiang et al., 2020). In other words, while the approach of~~  
595 PIREN-Seine (<https://www.piren-seine.fr/en>) research program followed laboratory incubation experiments (Servais et al., 1995) ~~, it appears today that the coupling between measurement networks and modeling makes it possible to approach the functioning of the systems in a more dynamic way (Wang et al., 2022).~~

## 5 Conclusions

The objective of this work was to investigate the role of organic matter loadings to river systems and the physiology of bacteria  
600 in river metabolism during a summer non-bloom low-flow period. New parameters were introduced to account for repartition partitioning and degradation of OM. Then, the sensitivity of the C-RIVE model was analyzed against the newly introduced and the already existing model parameters. The following conclusions can be drawn from this study:

- The Sobol sensitivity analysis method proved very efficient in the identification of influential parameters on DO evolution in the C-RIVE model. Then, by fixing the interaction-inducing parameters, the influence of other parameters was  
605 assessed. This methodology may also be of interest for future sensitivity analysis where parameter interactions may hide the effect of other parameters;
- The river metabolism is dominated by bacterial activity at low flow during summer non-bloom periods. As a consequence, the net growth rate of bacteria ~~composed of,~~ that combines their maximum growth rate ( $\mu_{max,hb}$ ) and mortality rate ( $mort_{hb}$ ) is the most important parameter under different TOC concentrations; therefore, it is essential to have a better  
610 estimation of the variation ranges of the growth and mortality rates of bacterial communities;

- Model response is very sensitive to the biodegradable share of DOM (BDOM) contributed by the boundary conditions. The effect of this parameter prevails at higher bacteria net growth rates occurring during summer low-flow periods when the organic matter ~~attributable to human pressure~~ brought by urban outflows is abundant in the river;
- ~~The river metabolism is dominated by bacterial activity at low flow during summer non-bloom periods;~~
- 615 – Water quality monitoring networks shall continuously measure the influential parameters of this study in order to provide the water quality models with update values;
- More frequent sampling of autochthonous bacteria communities upstream and downstream of major urban areas and in majors WWTP and CSO effluents will be of considerable interest to validate time varying parameter values estimated by data assimilation frameworks;
- 620 – The results of this study provide a list of influential and non-influential parameters. The latter can be fixed at their average or preferred value as per the literature, and the former can be introduced to the data assimilation tools in order to estimate their temporal evolution ~~thanks to the~~ with assimilation of high-frequency ~~observed DO data;~~ DO data.
