

30 January 2023

Dear Editor:

Thank you for coordinating the review of our manuscript Variations of carbon flux at different time scales in a semi-fixed sandy land ecosystem in Horqin Sandy Land, China (**bg-2022-171**). In the rest of this letter, we have provided details of our responses to the review comments. We hope that these responses and the resulting changes will be acceptable, but we will be happy to work with you to resolve any remaining issues.

Sincerely,

Yuqiang Li (on behalf of all authors)

Reviewer 1

Biogeosciences

RE: Submission of the revised manuscript (No. **bg-2022-171**): Variations of carbon flux at different time scales in a semi-fixed sandy land ecosystem in Horqin Sandy Land, China

Dear Reviewer#1:

Thank you for your assistance in the review of our manuscript. We have revised the manuscript carefully according to your comments.

Our detailed responses to comments are presented in the remainder of this letter. All of revisions have been highlighted in red in the revised manuscript.

General comments:

I have carefully reviewed the manuscript of Niu et al on sandy land carbon fluxes and climate variability. The manuscript presents a five-year time series of standard eddy covariance carbon flux data (measured NEE with GPP and Reco estimated by accepted methods) and associated weather and soil profile data. The main novelty of the paper is the sandy land ecosystem, a degraded state of the Inner Mongolian grasslands produced by a combination of climate and land use factors. The manuscript presents a generalized exploration of the data and does not test any specific hypotheses.

We have added our two research hypotheses in the Introduction (Lines 135-137, 140-145 in the revision) and test the hypotheses (Lines 245-271, 307-317 in the revision).

The key conclusions of the paper, summarized in the latter half of the abstract, mostly repeat ideas that are well-established in semiarid ecosystem flux literature, such as the idea that many dryland ecosystems have mean annual $NEE \sim 0$ but pivot between carbon sinks/sources in wet/dry years. Or that precipitation, temperature and soil water content are “dominant controls.”

We have revised the Abstract to clarify the novelty of our study. First, there has been little research in our study area, which is an important ecological area of China. Second, our study was conducted at multiple time scales and thereby revealed changes in the dominant factors that affect *NEE* in response to changes in the time scale. We emphasized carbon flux changes in semi-fixed sandy land ecosystems during the period of recovery from severe desertification, which is a period that has received insufficient attention in the literature (115-121 in the revision).

In the end, I find myself unable to clearly answer the important referee question: “Do the results support the key points/conclusions?” because the results are relatively unstructured, and the key points are overly general. The presentation of the manuscript follows accepted guidelines for organization and formatting.

We have added our two research hypotheses in the Introduction (Lines 135-137, 140-145 in the revision) and have restructured the results to clarify how our results relate to the two research hypotheses and the impact of our study. In particular, we have strongly supported the importance of water availability during the growing season and changes in the impact of the environmental factors on carbon fluxes with changing time scales (Lines 245-271, 307-317, Fig. 3, Fig. 6, and Table 3 in the revision).

The writing contains numerous faults in English language usage, although I was able to follow the meaning in nearly all cases.

We have asked Geoffrey Hart (ghart@videotron.ca/geoff@geoff-hart.com), an English science editor with more than 35 years of experience, to ensure that the quality of the language will be acceptable. Please contact him if necessary to confirm that he has performed this work or if you have any questions about the nature of the work that he has done.

Figures are of medium to poor quality, both in terms of visual presentation (especially readability of high-frequency data) and of conceptual representation which is an indicator of the carbon sink or source in terrestrial ecosystems. Therefore, comprehending the dynamics processes and underlying mechanisms of *NEE* is a crucial issue in global change research.

We have added graphs of the variation of the carbon fluxes and their relationships with precipitation and soil water content in dry and wet years during the growing season (Fig. 3a-e in the revision), and have also added the relationship between monthly-scale environment factors and carbon fluxes (Fig. 6 in the revision).

Overall, my impression is that this manuscript is not suitable for publication due to a lack of clear, testable hypotheses (or clear goals). This deficit leads to other “downstream” problems including poorly-conceived figures. The literature cited is missing many major bodies of work from several other continents. I encourage the coauthors to examine the literature more extensively, identify key knowledge gaps that could be addressed with this dataset, and write a manuscript that leverages these

valuable data to advance understanding. Given the large number of single-site, multi year eddy covariance studies published over the last 25 years, some suggested avenues for enhancing novelty include 1) comparing/contrasting the sandy land flux behavior with other dryland sites. 1) For example, it appears that the mean annual precipitation and seasonal distribution of this site are quite similar to grassland sites in New Mexico and possibly Arizona, USA, but with very different temperatures; 2) Showing how these flux data change the (or do not change) what is presently assumed about fluxes from such regions using currently available tools (often ecosystem models and/or remote sensing).

We have added the two specific research hypotheses we used (Lines 135-137, 140-145 in the revision), and have compared the changes at our site with values from 5 previous studies (Lines 313-337 in the revision), and have added a discussion of the impacts of the changes of the environmental factors (precipitation, temperature, and solar radiation) on the carbon fluxes (Lines 339-352 in the revision). In terms of the literature review, we have cited 17 additional recent studies.

Although your suggestions for improving the novelty of our study are interesting, we note that novelty is not the only goal of research and not even the most important goal. Replication of previous research in under-studied regions is also a valid goal, and was the purpose of our approach. However, we have clarified the novelty of our research in the Abstract (see our response earlier in this letter). We have also added these novel aspects in the Introduction (115-121 in the revision).

Below are some specific comments included in the hope that they may be useful for advancing this work.

1.21: What is semi-fixed sandy land?

We have added a definition of semi-fixed sand (Lines 78-80 in the revision). In summary, this is based on the soil texture (sandy) and the vegetation cover.

Zhao, H. L., Zhao, R. L., Zhao, X. Y., Zhang, T. H.: Ground discriminance on positive and negative processes of land desertification in Horqin Sand Land (in Chinese), J. of Desert Research, 28, 8-15. http://210.72.80.159/jweb_zgsm/EN/Y2008/V28/I1/8, 2008.

2. 25-29: This part would be stronger if it were framed around hypothesis testing. Instead, the writing focuses us on a few statistical techniques for assessing variable importance. What new knowledge is produced by this study that is transferable to other times and places?

We have revised this description to clarify that we examined the effects of seasonal-scale and inter-annual values of the environmental factors on carbon fluxes (Lines 285-327 in the revision). We have added our two research hypotheses (Lines 135-137, 140-145 in the revision) and restructured the results to support these hypotheses (Lines 245-271, 307-317, Fig. 3, Fig. 6, and Table 3 in the revision).

3. 29-32: This is all well-known from many other dryland studies.

We have deleted the well-known information in the revision.

4. Since the mean annual NEE = zero (within the uncertainties of the method), there could be more interest in evaluating the magnitude of the deviations from the mean (e.g. source and sink function in dry and wet years).

Because *NEE* responded differently in different years, relying on the overall average could be misleading. Although we have retained that data, we have clarified that the important differences in our study were between the wet and dry years (Lines 22-26, 460-463 in the revision).

5. 45: As a result of what? The prior sentence talks about how NEE is mathematically related to GPP and Reco, but it does not logically follow that these relationships establish a reason that understanding NEE is crucial.

We have clarified that *NEE* is crucial because it reflects the balance between photosynthesis and respiration and thus, affects whether a site will be a carbon source or sink (Lines 44-47 in the revision).

6. 62: This is a potentially promising topic for development of new knowledge, if the manuscript focuses on testing controlling mechanisms for sandy lands, especially if there are different controls in sandy lands than for other semiarid ecosystems.

We have clarified that our study focused on the control mechanisms at a desertified sandy site that is recovering from degradation. Our goal was not to compare our results with other sites during our study (to do so, we would have needed to add a second site in our analysis), but we do perform that comparison in the Discussion, where we have added citations of 5 studies to provide a comparison (Lines 339-352 in the revision).

7. 72; please define semi-fixed sands.

We have defined this term in Lines 78-80 in the revision.

Zhao, H. L., Zhao, R. L., Zhao, X. Y., Zhang, T. H.: Ground discrimination on positive and negative processes of land desertification in Horqin Sand Land (in Chinese), *J. of Desert Research*, 28, 8-15. http://210.72.80.159/jweb_zgsm/EN/Y2008/V28/I1/8, 2008.

8. 74: was a carbon source

We have changed this to “carbon source” in the revision (Line 83).”

9. 113: I am trying to determine what to expect that is new and different in this study as compared to the extensive body of literature in other semiarid ecosystems and as compared to the works cited here of Niu (2020, 2021) in sandy lands. Can this be made more clear?

We have clarified that the semi-fixed sandy land at our study site is recovering after severe ecosystem degradation leading to desertification, which is different from most previous studies of other semiarid ecosystems (Lines 62-66, 70-74, 114-132 in the revision). As compared to the works cited here of Niu (2020, 2021) in sandy lands, the main difference is the vegetation and land-use types (Lines 149-152 in the revision).

10. 169: I find these paragraphs very difficult to read, since they are packed with numbers and generally lacking any narrative thread to tie them together. It could be more effective to report means and ranges in a table and then use the text to illustrate key features of the data (features related to testing the study hypotheses, such as extreme seasons/years)

We have removed the redundant data and only show the most important data that are most relevant to the study. We have revised the description related to Figure 2 and Table 2 (lines 223-243 in the revision).

11. 170: to my understanding, describing a solar-cycle time series as a unimodal distribution is not appropriate, because a time series (which may be unimodal) is a sequence, not a distribution of (random) samples from a population.

We have changed our description to “unimodal trends”, since we show the trends over time rather than a statistical distribution graph (Line 224 in the revision).

12. 190: VPD is an example of a mechanistic control with potential to be explored. Is there a hypothesis related to VPD? See, for example, recent papers by Kim Novick on this topic and specifically the inferences related to drylands with respect to canopy flux controls by VPD vs. SWC.

We have carefully read the literature that you recommended and analyzed how *VPD* influences the carbon fluxes. Because *VPD* was not a major factor that affected the carbon fluxes in our study ecosystem, we did not add a discussion of its mechanisms and have instead retained the original description (Lines 239-243 in the revision).

13. 194: this paragraph is mostly generalizations, such as "showed obvious seasonal changes." It would be better to describe what these dynamics are. Better yet, refer to Figure 3 for the dynamics and use the text to point out key features related to the study questions.

We have added more specific descriptions of the seasonal changes (Lines 245-250 in the revision).

14. 216: it would be more compelling to lead with the study hypotheses and then use the statistical techniques to test the hypotheses.

We have added our two research hypotheses (Lines 135-137, 140-145 in the revision) and restructured the results to support our hypotheses (Lines 245-271, 307-317, Fig. 3, Fig. 6, and Table 3 in the revision).

15. Figure 2 and Figure 3: While the figures contain valuable information, the high frequency nature, many time series, many panels, and 5-year coverage period makes it difficult to discern anything meaningful beyond what we could learn from a table of climate variables. If there key study hypotheses being tested that depend upon these variables (e.g. wet vs. dry years, or SWC variability at differing depths), the figures

should highlight the key aspects of these datasets.

We included Figure 2 to show the changes of meteorological factors throughout the study period to reveal important environmental similarities and differences between years (i.e., factors that do or don't explain differences in the carbon fluxes). However, we have added Figure 3 to show the changes of the three carbon fluxes during the same period and their relationships with precipitation and soil water content during the growing season in representative dry and wet years to clarify these relationships. We also added an analysis of the relationships between the monthly-scale environmental factors and the carbon fluxes (Fig. 6 and Table 3 in the revision).

16. Figure 4: This figure with monthly values could potentially provide some interesting ideas for hypotheses to test. For example, the large GPP and carbon sink NEE in summer 2021 might inspire a figure or other analysis relating monthly fluxes to key hypothesized controls.

Based on the monthly-scale values of the three carbon fluxes in Figure 4, we have added Figure 6 and Table 3 to describe the relationships between the monthly-scale environmental factors and the three carbon fluxes during the growing season, and we discuss how these environmental factors affected *GPP*, *NEE* and *R_{eco}* (Lines 356-368 in the revision).

17. Figure 6 strikes me as rather oversimplified, and I struggle to learn anything new from this figure. The fits are generally poor, and the time scales might not even make sense. For example, a scatterplot of high-frequency data like this does not account for the Birch Effect, in which the largest respiration values in dryland ecosystems often follow (lag) by several days, pulses in SWC. Graphical tests of key drivers (e.g. GPP vs. SWC at 3 depths) might be more tractable at the monthly scale, as suggested by the interesting results for summer 2021 in Figure 4.

We have deleted the high-frequency data at a daily scale and have replaced them with the relationship between the monthly-scale environmental factors and the three carbon fluxes during the growing season (Fig. 6 and Table 3 in the revision).

18. Figure 7-9: This shows some potentially interesting results, but there are problems with this figure. First, it does not follow from any hypotheses posed in the introduction about the key controls. Second, lines are fit to data that are apparently nonlinear. For example, panel a shows a flat response of NEE to Ts50 between -8C and +8C, and then a declining relationship, and there is likely ecological meaning in that nonlinear patterns. Second, these simple scatter plots do not seem to account for the seasonality of the ecosystem. In other words, we are presented the relationship between SWC and NEE in all months of the year, when we have major reasons to expect different relationships within the growing season or outside it. One suggestion for improving this analysis would be to present a bivariate relationship (like these ones) that is screened for a given range of values in other variables. For example, plot GPP vs. SWC for Ts50 between 5-10 C (or whatever might make sense). Or plot GPP vs. SWC for summer growing

season only.

We have replaced Figures 7 to 9 in the original manuscript with the relationships between the monthly-scale environmental factors and the three carbon fluxes during the growing season (Fig. 6 and Table 3 in the revision). In addition, we used nonlinear regression for some of the graphs in Figure 6 where that provided a better fit. We then discuss these relationships in terms of the research hypothesis. In summary, the effects of drought during the growing season were most important, and this was revealed in the long-term (annual) time scale (Lines 245-271, 307-327 in the revision).

19. Table 1: this is a valuable table. Please express significant digits such that they represent the true uncertainty. For example, Uncertainty in precipitation measurements with a tipping bucket gauge can range from 5-15% or more. Therefore, $P = 312.80$ mm, which communicates precision to 1×10^{-5} m, is not reasonable. Perhaps 312 or 310 or 300 would be more representative. Please consider this for each variable shown.

As you note, providing multiple decimal places of precision may not be appropriate. We have therefore presented the precipitation values as integers (Lines 233-234, Table 2 in the revision). Calculating the optimal precision (integers versus values expressed to the nearest 2 or 10 mm) would be beyond the scope of our study.

Suggested reading:

In addition to the valuable works cited herein, mainly focused on China sites, there exists extensive literature on semiarid fluxes by the eddy covariance method across multiple other continents. Please see for example the following short list and the references in these papers:
