26 **Abstract**

27 Present and historical climate conditions jointly determine contemporary biodiversity patterns and  
28 ecosystem functions. However, it remains unclear how contemporary climate and paleoclimate  
29 changes together affect the three dimensions of biodiversity (i.e., taxonomic diversity, functional  
30 diversity and phylogenetic diversity) and their relationship with ecosystem functions. Here, we  
31 assess the impact of current climate, paleoclimate and its anomalies on contemporary biodiversity  
32 and ecosystem functions. We estimated the taxonomic, functional and phylogenetic diversity of  
33 grassland on the Mongolian Plateau using vegetation survey data and trait information. We then used  
34 Random Forest and Structural Equation models to assess the relative importance of the present, the  
35 Mid-Holocene and the Last-Glacial Maximum climate as well as paleoclimate changes as  
36 determinants of diversity and aboveground biomass. Our results showed that paleoclimate changes  
37 and modern climate jointly determined contemporary biodiversity patterns, while community  
38 biomass was mainly affected by modern climate, namely the aridity index. Modern aridity and  
39 temperature were two major influences on all three dimensions of biodiversity. Mid-Holocene  
40 climate anomalies had a strong effect on species richness and phylogenetic diversity, while  
41 functional diversity was mainly affected by temperature anomalies since the Last Glacial Maximum.  
42 These findings suggest that contemporary biodiversity patterns may be affected by processes at  
43 divergent temporal scales. Our results show that simultaneously exploring the response of the three  
44 dimensions of biodiversity in different periods of climate change and the theoretical framework for

45 its impact on community biomass is helpful to provide a more comprehensive understanding of  
46 patterns of biodiversity and its relationship with ecosystem functions.

49 diversity, taxonomic diversity

#### 50 **1. Introduction**

51 Global climate changes, such as increasing temperature and changing precipitation, are altering  
52 biodiversity patterns at an unprecedented rate, and have serious consequences for ecosystem  
53 functions related to biodiversity changes (Mottl et al., 2021; Nolan et al., 2018; Ye et al., 2019).  
54 Ecosystem functioning associated with biodiversity, and contemporary diversity patterns and their  
55 relationships may be regulated by modern climate, past climate and climate change (Fordham et al.,  
56 2020; Eiserhardt et al., 2015; Svenning et al., 2015).

57 Ecosystem functions are strongly influenced by biodiversity (Isbell et al., 2011; Hooper et al.,  
58 2005), but understanding the effects of different dimensions of biodiversity (i.e., taxonomic diversity,  
59 functional diversity and phylogenetic diversity) on ecosystem functions is still a challenge in ecology  
60 (Van Der Plas, 2019; Cadotte et al., 2008; Swenson, 2011). Traditionally, most studies of biodiversity  
61 and ecosystem functions have predominantly focused on the relationship between taxonomic  
62 diversity (i.e., species richness) and biomass or productivity. However, only considering taxonomic  
63 diversity has the limitation that it may ignore important ecological processes such as the formation of  
64 function traits or the evolutionary history of species (Flynn et al., 2011; Swenson, 2011). The  
65 importance of taking into account other aspects of biodiversity, including functional diversity and  
66 phylogenetic diversity, has increasingly been recognized. The effects of plant functional diversity on

67 ecosystem functioning are largely driven by variations in plant functional traits, such as adult plant  
68 height and leaf size (Diaz et al., 2016). Phylogenetic diversity (PD) is a key driver of community  
69 assembly and ecosystem functions (Srivastava et al., 2012; Cavender-Bares et al., 2009). Previous  
70 research had shown that PD may be a better metric than species richness or functional diversity for  
71 predicting plant biomass (Cadotte et al., 2008). Communities with higher PD have stronger  
72 anti-interference ability because of their evolutionary potential to adapt to changing environmental  
73 conditions. However, the role of multi-dimensional biodiversity in driving ecosystem functions in  
74 response to climate change still needs further research. Elucidating the impacts of multi-dimensional  
75 biodiversity on biomass in a changing world can deepen our understanding of the direct and indirect  
76 effects of changes in climate and biodiversity on terrestrial ecosystems, and improve predictions of  
77 the ecological consequences of global climate changes.

78 Changes in community biodiversity and composition caused by climate change have been  
79 explored in various ecosystems (Avolio et al., 2021), including tropical forests in the Amazon  
80 (Esquivel-Muelbert et al., 2019), alpine meadows on the Qinghai-Tibet Plateau (Liu et al., 2018a)  
81 and a heterogeneous California grassland (Harrison et al., 2015). Dispersal limitation and  
82 environmental filtering (i.e., climatic conditions and paleoclimate change) play an important role in  
83 sorting species from the global species pool and in shaping large-scale diversity patterns (Kubota et  
84 al., 2018; Liu et al., 2021). Many studies have found that climate changes in the Mid-Holocene and  
85 the Quaternary interglacial period are the main driving factors of current species distribution,  
86 functional traits and community phylogeny (Svenning and Skov, 2007b). The current patterns of  
87 species richness and distribution of European flora are jointly affected by contemporary climatic  
88 conditions and climate change during the Late Quaternary glacial-interglacial period (Svenning and

89 Skov, 2007a; Svenning and Skov, 2007b). Contemporary plant functional traits and composition are  
90 highly sensitive to climate and influenced by climate from tens of thousands of years ago, with  
91 important consequences for ecosystem functions (Blonder et al., 2018; Butler et al., 2017). For  
92 example, in Europe patterns of plant functional diversity exhibited prominent glacial-interglacial  
93 climate change imprints (Ordonez and Svenning, 2015; Ordonez and Svenning, 2017). This is partly  
94 due to the non-random removal of functional combinations that may have occurred during the  
95 Last-Glacial Maximum (LGM; ~21,000 years ago), increasing functional differences between native  
96 and migratory species, leading to smaller and dispersed functional spaces (Ordonez and Svenning,  
97 2017). Evidence derived from the fossil pollen sequence and ecological datasets has shown that the  
98 acceleration of biodiversity changes began millennia ago, whereas vegetation changes during the  
99 Late Pleistocene to Early Holocene were driven primarily by changing climate (Mottl et al., 2021). In  
100 the South American tropics, the species composition and structure of Last Glacial Maximum forests  
101 were quite different from those of today, and biomass was also lower than that of contemporary  
102 forests (Mayle et al., 2009).

103 Furthermore, the effects of climate change on biodiversity should depend partly on climate  
104 displacement rate (climate-change velocity) (Sandel et al., 2011). For example, phylogenetic  
105 clustering increased with increasing intensity of Quaternary glacial-interglacial climatic oscillations  
106 in South America and Africa (Kissling et al., 2012). There is evidence that vegetation changes in  
107 Northern Europe were non-linear and varied greatly among regions in the early-Mid Holocene  
108 (Seddon et al., 2014). Paleoclimate simulations since 21,000 years B.P. suggest that there are great  
109 similarities between past and future temperature changes in Eurasian temperate grasslands (Fordham  
110 et al., 2020). During the last glacial-interglacial transition period, global warming and related climate

111 change led to changes in ecosystems to a degree comparable to the predicted warming under future  
112 high-emission scenarios (Nolan et al., 2018). Therefore, studying the impact of past climate and its  
113 effects on contemporary biodiversity patterns will help us understand the potential effects of future  
114 climate changes. However, most studies exploring the impact of present climate and paleoclimate  
115 drivers on ecosystem functions have focused on forest ecosystems, while grassland ecosystems  
116 remain understudied. In addition, it is not yet clear whether taxonomy, function and phylogenetic  
117 diversity will vary with climate gradients and climate changes, and the intensity of any such changes  
118 remain unclear. Therefore, there is an urgent need to consider the impact of current climate,  
119 paleoclimate and its anomalies on contemporary biodiversity and ecosystem functions.

120 The Mongolian Plateau is located in the arid and semi-arid area of eastern Eurasia. Our previous  
121 research has shown that climate is an important direct factor mediating the relationship between  
122 species richness and aboveground biomass in the Mongolian plateau steppe (Li et al., 2021; Li et al.,  
123 2020). However, in the Late Quaternary, the Mongolian Plateau experienced severe alternating dry  
124 and wet climatic fluctuations (Maestre et al., 2021; Tian et al., 2017), which may have a significant  
125 impact on current plant diversity and ecosystem function. However, the impacts of climate in  
126 different periods and climate legacy effects on aboveground biomass of steppes in the Mongolian  
127 Plateau, as well as whether these effects are biodiversity dependent, remain to be evaluated. To  
128 address these knowledge gaps, we coupled data from a field survey of 152 sites in the Mongolian  
129 Plateau (Fig. S1) to existing databases on present and past climates to explore present climate and the  
130 legacy effects of climate during the Last Glacial Maximum and the Mid-Holocene on current  
131 biodiversity and biomass.

132 Here, we aim to evaluate the relative importance of taxonomic, functional, and phylogenetic

133 diversity on community biomass of steppe in the Mongolian Plateau, and to assess whether and how  
134 climate in different periods and their changes affect the three dimensions of diversity, and their  
135 relationships with community biomass. We specifically ask: (1) Do the three dimensions of diversity  
136 affect community biomass, and if so, to what extent? (2) Whether and how climate at divergent  
137 temporal scales and paleoclimatic changes affect different dimensions of biodiversity? And (3) If  
138 there are effects, how do they affect the biodiversity-biomass relationship?

## 139 **2. Materials and Methods**

### 140 **2.1 Study Area**

141 We conducted field surveys in the grasslands of the Mongolian Plateau, including Inner Mongolia  
142 Autonomous Region in China and Mongolia, during June to August of 2014~2018 (Fig. S1). The  
143 Mongolian Plateau is located in the eastern part of Eurasia, with a geographic range of 37.61 °to  
144 53.35 °N, 87.83 °to 125.95 °E, and an elevation range from 85 m to 4203 m a.s.l. (above sea level).  
145 The mean annual temperature (MAT) of the study region ranges from -12 °C to 10 °C and mean  
146 annual precipitation (MAP) ranges from 26 mm to 641 mm.

### 147 **2.2 Data Collection**

#### 148 **2.2.1 Sites Sampled and Vegetation Investigation**

149 We investigated 152 grassland sites set in flat areas with little human interference and a relatively  
150 homogeneous environment. “Little human interference” mainly refers to the selection of areas with  
151 less human activities such as grazing for investigation. Specific indicators include the following  
152 aspects: 1) Avoid choosing areas with manure of cattle and sheep; 2) Dominant species such as  
153 *Leymus chinensis*, *Stipa* spp. are eaten less by livestock; 3) There were fewer degradation indicators.  
154 It mainly refers to the decrease in the number of established species or dominant species in the

155 grassland, while the degeneration indicator plants such as *Convolvulus ammannii*, *Potentilla acaulis*,  
156 *Artemisia frigida*, *Stellera chamaejasme* and *Cynanchum hancockianum* appeared in large numbers.  
157 These sites were separated by about 50 km. According to the methods and protocols for plant  
158 community inventories proposed by Fang et al. (Fang et al., 2009), most of the vegetation surveys in  
159 this study were conducted by setting one 10 m x 10 m quadrat at the respective site. However, in a  
160 few areas with sparse vegetation and large heterogeneity, we set three 10 m × 10 m quadrats to  
161 ensure the accuracy of the survey data.. Within each quadrat, five 1 m × 1 m plots were placed at  
162 each corner and at the center of the quadrat to investigate vegetation. A total of 296 vascular plant  
163 species were recorded.

164 We measured species height, density, coverage and standing biomass of each species in each  
165 plot. Three 1 m × 1 m plots along the diagonal line 10 m × 10 m quadrat were selected from the five  
166 plots to measure the standing biomass of each species. Plant species were cut at ground level and  
167 separately bagged, then oven-dried at 65 °C to constant weight, and weighed for dry matter.

### 168 **2.2.2 Climate Data**

169 Mean annual temperature (MAT, °C) and mean annual precipitation (MAP, mm) were obtained from  
170 the CHELSA database (Climatologies at High Resolution for the Earth's Land Surface Areas,  
171 <http://chelsa-climate.org/>) (Karger et al., 2017), a data set consisting of monthly temperature and  
172 precipitation climatology from 1979 to 2013. Potential evapotranspiration (PET) was obtained from  
173 the CGIAR-CSI (CGIAR Consortium for Spatial Information, <http://www.cgiar-csi.org>) based on  
174 latitude and longitude data for each site (Trabucco and Zomer, 2019). The resolution of both is 30 arc  
175 seconds. Aridity was measured using the aridity index (AI,  $AI = MAP / PET$ ). Higher AI values  
176 indicate lower aridity and higher humidity. Paleoclimate data were downloaded from Worldclim

177 (<http://worldclim.com/paleo-climate1>) with a resolution of 2.5 minutes. The database was made  
 178 available by CMIP5 (Coupled Model Intercomparison Project Phase 5) and was calibrated based on  
 179 the current climate using WorldClim 1.4. The MAT and MAP of the Mid-Holocene (MID, about  
 180 6000 years ago) and the Last Glacial Maximum (LGM, about 22,000 years ago) were simulated  
 181 based on CCMS4 (Community Climate System Model version 4). Climate anomaly (i.e., present-day  
 182 values minus paleoclimate values) was used to indicate the degree of climate change since the MID  
 183 and the LGM (Sandel et al., 2011). Temperature-change velocity from the LGM to the present  
 184 (velocity, m/yr) was obtained from DRYAD (<https://datadryad.org>) (Sandel et al., 2011). The climate  
 185 variables used in this study are shown in Table 1.

186 **Table 1 Climate variables included in this study**

	Climate variables	Abbreviation
The present climate (1979-2013)	Mean annual precipitation of the present	MAP
	Mean annual temperature of the present	MAT
	Aridity index of the present	AI
The Mid-Holocene climate	Mean annual precipitation of the Mid-Holocene	MAP <sub>mid</sub>
	Mean annual temperature of the Mid-Holocene	MAT <sub>mid</sub>
The Last Glacial Maximum climate	Mean annual precipitation of the Last Glacial Maximum	MAP <sub>lgm</sub>
	Mean annual temperature of the Last Glacial Maximum	MAT <sub>lgm</sub>
Paleoclimate change	MAP anomaly from the Mid-Holocene to the present	AMAP <sub>mid</sub>
	MAT anomaly from the Mid-Holocene to the present	AMAT <sub>mid</sub>
	MAP anomaly from the Last Glacial Maximum to the present	AMAP <sub>lgm</sub>
	MAT anomaly from the Last Glacial Maximum to the present	AMAT <sub>lgm</sub>

---

### 187 **2.2.3 Plant functional traits**

188 The functional traits of each plant species include growth form, life form, phyllotaxy, single or  
189 compound leaf, petiole, inflorescence, fruit type, flowering period, fruit ripening period, length of the  
190 flowering period, water ecotypes, leaf length, leaf width and plant height (Table S1). These traits  
191 were looked up in the Flora of Inner Mongolia (Third Edition) or Flora of China (Online Edition)  
192 (<http://www.iplant.cn/frps>). The trait data for leaf length and leaf width were the mean values  
193 provided in Flora of China (Fig. S2). For example, if the leaf length of *Leymus chinensis* was  
194 described as 7-18 cm in the Flora of China, then leaf length was defined as 12.5 cm.

### 195 **2.3 Aboveground biomass**

196 The aboveground biomass of the community was calculated based on the dry matter accumulation  
197 value ( $\text{g/m}^2$ ) of all plant samples in each plot, and the average aboveground biomass of each plot in  
198 each quadrat was calculated to represent the aboveground biomass of the plant community ( $\text{g/m}^2$ ).

### 199 **2.4 Diversity calculations**

#### 200 **2.4.1 Taxonomic diversity**

201 We used species richness (SR), Shannon-Wiener index and Pielou index as measures of community  
202 taxonomic diversity. The species richness (number of species/ $\text{m}^2$ ) at each site was calculated as the  
203 average number of species per plot. The Shannon-Wiener index and Pielou index were calculated  
204 using the ‘diversity’ function in the “*vegan*” R package (Oksanen et al., 2020).

#### 205 **2.4.2 Functional diversity**

206 The functional richness (FRic), functional evenness (FEve), functional divergence (FDiv), functional  
207 dispersion (FDis) and Rao index (Rao’s Q) were calculated based on the Gower distance of

208 functional traits using the ‘dbFD’ function in the ‘FD’ R package (Lalibert é et al., 2015).

### 209 **2.4.3 Phylogenetic diversity**

210 All plant species names recorded in surveys were checked in the plant list ([www.theplantlist.org](http://www.theplantlist.org)) to  
211 obtain acceptable species names. Based on the APG III system (The Angiosperm Phylogeny Group,  
212 2009), we entered the taxonomic information (family/genus/species) of all species into the  
213 Phylomatic online plant database (Phylomatic Version 3, <http://phylodiversity.net/phyloomatic/>),  
214 selected storedtree = “zanne2014 (Zanne et al., 2014)”, and output a phylogenetic tree with branch  
215 length and differentiation time (Fig. S2). Faith’s phylogenetic diversity (PD, the sum of the  
216 phylogenetic branch lengths), the mean pairwise distance (MPD) and the mean nearest taxon  
217 distance (MNTD) between species in a community were calculated using the ‘mpd’ function in the  
218 ‘*picante*’ R package (Kembel et al., 2010).

### 219 **2.5 Data analysis**

220 First, we conducted a Random Forest model to estimate the relative importance of the three  
221 dimensions of biodiversity to community biomass. The Random Forest model can alleviate  
222 multicollinearity and complex interactions between independent variables. We built 5000 regression  
223 trees in Random Forest, and each tree was fitted with 2/3 of the data. The other 1/3 of the data was  
224 used to estimate the importance of each predictor variable, which was represented by the increase in  
225 mean square error (MSE). In the Random Forest model, the variables that ranked first in terms of  
226 taxonomic, functional and phylogenetic diversity were selected as proxies for the three dimensions of  
227 biodiversity.

228 To explore the influence of climate in different periods and climate anomalies on biodiversity,  
229 we also used the Random Forest model to analyze the relative importance of the present climate, the

230 Mid-Holocene climate, the Last Glacial Maximum climate, and paleoclimate change on the three  
231 dimensions of biodiversity. To evaluate the relative importance of climate drivers of biodiversity, we  
232 calculated the ratio between the increase in MSE of the predictor and the sum of all the increases in  
233 MSE, which is expressed as a percentage.

234 To study the effects of climate in different periods and climate anomalies on biodiversity and  
235 aboveground biomass, we performed piecewise structural equation models (pSEM) to test the direct  
236 and indirect causal relationships between the climate in different periods and paleoclimate change,  
237 species diversity, functional diversity, phylogenetic diversity and biomass. Model construction  
238 procedures involved the following three stages. First, based on the results of the Random Forest  
239 model, we identified the climate variables that significantly affected biodiversity and divided them  
240 into composite variables. The model contained two composite variables that potentially represent  
241 collections of variables in terms of the present climate and paleoclimate change. We calculated  
242 Pearson correlations between the climate factors (Fig. S3) and deleted the predictors with high  
243 correlation coefficients ( $>0.85$ ,  $P < 0.05$ ) to avoid multicollinearity. Before pSEM analysis, all  
244 selected predictors were standardized. Second, principal component analyses (PCAs) were used for  
245 the composite variables with multiple predictors. For each composite variable, the first principal  
246 component (PC1) explained 64~71% of the total variance and was used in the subsequent pSEM  
247 analysis (Table S2). Third, pSEM was developed from the full conceptual model (Fig. S4). We fitted  
248 the component models of the piecewise SEM as linear models and reported the standardized  
249 coefficient for each path from each component model. We used Shipley's d-separation test and  
250 Fisher's C statistic to evaluate the overall fit of the pSEM, and Akaike information criteria (AIC) to  
251 select the best model. We used standardized path coefficients to measure the direct, indirect, and total

252 effect sizes of the present climate and paleoclimate changes on AGB.

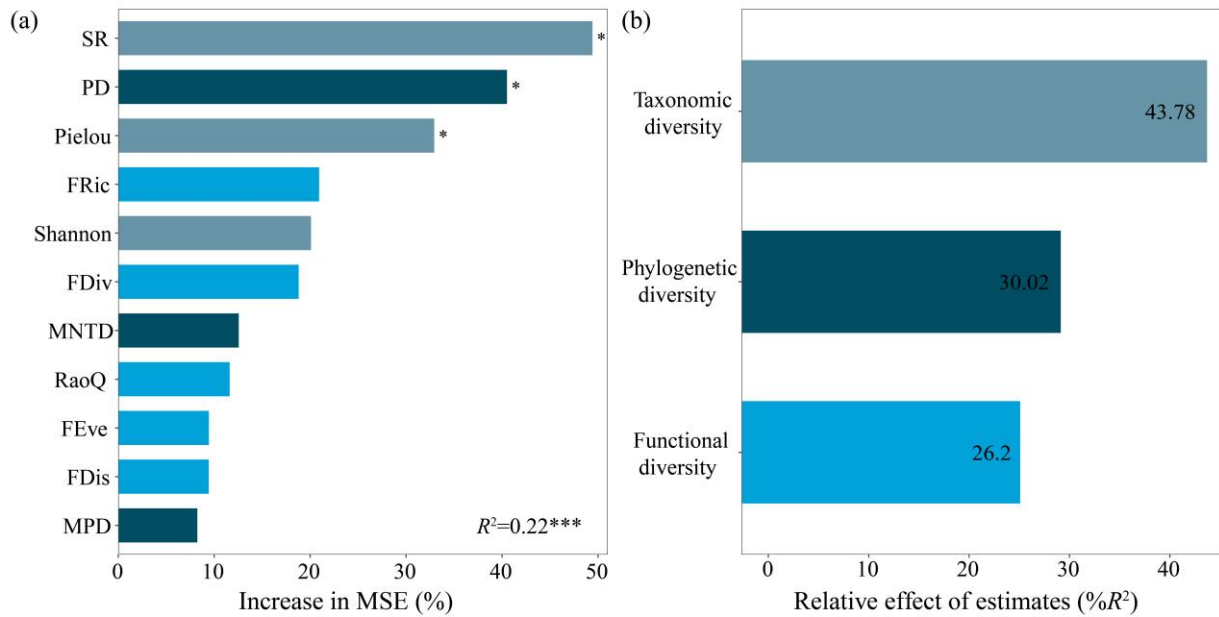

253 We conducted all analyses in R x64 4.0.5. The Random Forest model was conducted using the  
254 ‘randomForest’ function in the ‘*randomForest*’ package (Cutler et al., 2007; Breiman et al., 2018),  
255 and the significance of the variables was tested using the ‘rp.importance’ function in the ‘*rfPermute*’  
256 package (Archer, 2016). PCA was performed using the ‘princomp’ function in the ‘*psych*’ package in  
257 R (Revelle, 2021). Piecewise structural equation modeling was conducted and tested using the  
258 ‘*piecewiseSEM*’ package (Lefcheck, 2020; Lefcheck and Freckleton, 2015).

### 259 **3. Results**

#### 260 **3.1 Effects of biodiversity on aboveground biomass**

261 Among the 11 biodiversity variables, SR, PD and Pielou index identified by the RF model were the  
262 three most significant predictors influencing aboveground biomass (Fig. 1a). Taken together,  
263 taxonomic diversity represented by SR, Pielou and Shannon-Wiener index collectively contributed  
264 43.78% to the RF model for aboveground biomass, while phylogenetic diversity represented by PD  
265 (including MNTD and MPD) and functional diversity represented by FRic (including FDiv, FEve,  
266 FDis and RaoQ) contributed 30.02% and 26.2%, respectively (Fig. 1b).

267 Based on the ranking results from the Random Forest model, SR, PD, and FRic were selected as  
268 agents of taxonomic, phylogenetic, and functional diversity, respectively, and used for subsequent  
269 analysis.

281

Fig. 1 The importance (a) and relative contributions (b) of the three dimensions of biodiversity to community biomass. An increase in mean square error (MSE) denotes an increase in the percentage mean square error. Significance levels are as follows: \*:  $P < 0.05$  and \*\*\*:  $P < 0.001$ .

### 3.2 Paleoclimate and present climate predictors of contemporary diversity

Random Forest models explained 35% (cross-validation  $R^2 = 0.35$ ,  $P < 0.001$ ), 31% (cross-validation  $R^2 = 0.31$ ,  $P < 0.001$ ) and 31% (cross-validation  $R^2 = 0.31$ ,  $P < 0.001$ ) of the variance in SR, PD and FRic, respectively (Fig. 2). Temperatures in different periods, including  $MAT_{mid}$ ,  $MAT$  and  $MAT_{lgm}$ , were the main factors driving SR and PD ( $P < 0.05$ , Fig. 2a and 2b), followed by climate anomalies in various periods. However, the current climate (i.e., AI, MAT and MAP) had a stronger impact on FRic ( $P < 0.05$ , Fig. 2c).

An increase in mean square error (MSE) denotes an increase in the percentage mean square error. Significance levels are as follows: \*:

$$P < 0.05 \text{ and } ***: P < 0.001.$$

In terms of relative contributions, the current climate and the paleoclimate changes had greater impacts on the three dimensions of biodiversity. Paleoclimate change was the best predictor of SR (33.90%) and PD (32.10%). Strikingly, the present climate (38.68%) showed a larger contribution to the prediction of FRic than paleoclimate change (26.06%; Fig. 3).

### 3.3 Influence of climate factors on biodiversity and aboveground biomass

296

The present climate, MAT of the Mid-Holocene and the Last Glacial Maximum, and paleoclimate

297

change explained 38% ( $R^2 = 0.38$ ), 33% ( $R^2 = 0.33$ ), 36% ( $R^2 = 0.36$ ) and 29% ( $R^2 = 0.29$ ) of the

298

variances in SR, PD, FRic and AGB, respectively (Fig. 4). The present climate had direct and

299

indirect significant associations with AGB via all biodiversity variables (Fig. 4). The present climate

300

was significantly and positively associated with SR ( $r_{\partial} = 0.46$ ,  $P < 0.05$ ), PD ( $r_{\partial} = 0.35$ ,  $P < 0.05$ )

301

and FRic ( $r_{\partial} = 0.58$ ,  $P < 0.05$ , Fig. 4). However, the paleoclimate change had direct significant

302

negative effects on SR ( $r_{\partial} = -0.28$ ,  $P < 0.05$ ), PD ( $r_{\partial} = -0.32$ ,  $P < 0.05$ ) and FRic ( $r_{\partial} = -0.25$ ,  $P < 0.05$ ,

303

Fig. 4).  $MAT_{mid}$  and  $MAT_{lgm}$  had no significant effects on SR, PD, FRic and AGB (Fig. 4).

304

305 Fig. 4 SEMs fitted to the effects of climate in different periods and paleoclimate change on diversity

306 and AGB. The present climate is PCA component 1 of the AI and MAT. The paleoclimate change

307 represents a composite variable including MAT anomaly from the Mid-Holocene to the present,

308 MAT and MAP anomaly from the Last Glacial Maximum to the present. Numbers adjacent to arrows

309 represent the standardized path coefficients ( $r_{\partial}$ ).  $R^2$  indicates the proportion of variance explained.

310 Blue (positive paths) and orange (negative paths) solid arrows indicate significant paths ( $P < 0.05$ ),

311 and gray dashed arrows indicate non-significant paths ( $P > 0.05$ ).

312

313 For the present climate, the direct effects of AI on SR ( $r_{\partial} = 0.33$ ,  $P < 0.05$ ), PD ( $r_{\partial} = 0.27$ ,  $P <$

314  $0.05$ ), FRic ( $r_{\partial} = 0.49$ ,  $P < 0.05$ ), and AGB ( $r_{\partial} = 0.37$ ,  $P < 0.05$ ) were all significantly positive, while

315 the direct effects of MAT on the three dimensions of biodiversity (SR,  $r_{\partial} = -0.34$ ; PD,  $r_{\partial} = -0.36$ ;

316 FRic,  $r_{\partial} = -0.29$ ;  $P < 0.05$  in all cases) were all significantly negative (Fig. 5). In addition, SR ( $r_{\partial} =$

317  $-0.25$ ,  $P < 0.05$ ) and PD ( $r_{\partial} = -0.25$ ,  $P < 0.05$ ) were negatively affected by MAT anomaly from the

318 Mid-Holocene to the present ( $AMAT_{mid}$ ), but FRic ( $r_{\partial} = -0.23$ ,  $P < 0.05$ ) was mainly driven by MAT

319 anomaly from the Last Glacial Maximum to the present ( $AMAT_{iglm}$ ; Fig. 5). AI accounted for the

320 largest proportion of variation in AGB (80.06%), followed by MAT at 10.81% (Table 2). The direct  
 321 effect ( $r_{\theta} = 0.37$ ) of AI on AGB was greater than the indirect effect ( $r_{\theta} = 0.12$ , Table 2).

322  
 323 Fig. 5 The effects of present climate (AI and MAT) and paleoclimate change (AMAT<sub>mid</sub> and  
 324 AMAT<sub>lgm</sub>) on diversity and AGB. Numbers adjacent to arrows represent the standardized path  
 325 coefficients. R<sup>2</sup> indicates the proportion of variance explained. Blue (positive paths) and orange  
 326 (negative paths) solid arrows indicate significant paths ( $P < 0.05$ ), and gray dashed arrows indicate  
 327 non-significant paths ( $P > 0.05$ ).

328 Table 2 The direct, indirect, total effects and the relative contribution of the present climate and  
 329 paleoclimate change on AGB in the structural equation model

Variables	Direct effect	Indirect effect	Total effect	Relative contribution (%)
AI	0.37	0.12	0.49	80.06
MAT	0	-0.07	-0.07	10.81
AMAT <sub>lgm</sub>	0	-0.03	-0.03	4.95
AMAT <sub>mid</sub>	0	-0.03	-0.03	4.18

## 330 **4. Discussion**

### 331 **4.1 The effects of different dimensions of biodiversity on aboveground biomass**

332 Our research showed that, without considering the influence of climatic conditions, taxonomic  
333 diversity was the most important factor influencing the aboveground biomass of Mongolian Plateau  
334 grasslands, followed by phylogenetic diversity and functional diversity. However, a large number of  
335 studies have emphasized the importance of phylogenetic diversity and functional diversity for  
336 ecosystem functions (Srivastava et al., 2012; Cadotte et al., 2008; Swenson et al., 2012). For example,  
337 research on subtropical forests in northern China showed that functional diversity is more important  
338 than taxonomic diversity in controlling aboveground biomass, which is related to the acquisitive  
339 resource use strategy of functional traits (Hanif et al., 2019). However, in Mongolian Plateau  
340 grasslands taxonomic diversity may be more critical. Selection effects and compensatory effects are  
341 the main mechanisms through which biodiversity impacts on biomass. The grassland community  
342 structure of the Mongolian Plateau is relatively simple, and biomass mainly depends on the number  
343 or dominance of dominant species. However, functional traits considered in this study, such as leaf  
344 size and plant height, do not have a strong impact on biomass. The Mongolian Plateau is located in  
345 an arid and semi-arid area, and drought-tolerant species invest a lot in seed resources, leaf structure  
346 and root biomass (Wolf et al., 2021). Studies have shown that these traits are negatively correlated  
347 with aboveground biomass, while functional traits consistent with growth strategies, such as leaf  
348 nitrogen concentration and photosynthetic utilization efficiency, can promote aboveground biomass  
349 (Wolf et al., 2021).

350 Secondly, phylogenetic diversity also had a significant impact on aboveground biomass.

351 Phylogenetic diversity contains the evolutionary information of species ecology. It is influenced by

352 the average degree of correlation between species and the number of existing species, and can reflect  
353 the evolutionary sequence of characteristics related to habitat and resource utilization (Srivastava et  
354 al., 2012). If species make better use of all available resources, productivity may increase. Therefore,  
355 our research suggests that protecting taxonomic diversity and conserving evolutionarily different  
356 species are equally important in effectively maintaining high-yielding communities.

#### 357 **4.2 Relationship between paleoclimate anomalies and current biodiversity patterns**

358 Although a rich body of research has explored the factors affecting biodiversity patterns and the  
359 relationship between biodiversity and biomass (Van Der Plas, 2019; Tilman et al., 2012) , it is not  
360 clear how current climate and paleoclimate together affect the relationship, especially in grassland  
361 communities. Here, our results showed that paleoclimate changes and present climate factors were  
362 critical variables influencing contemporary biodiversity patterns. This illustrates the importance of  
363 historical factors, such as evolution, as well as contemporary factors, such as climate, in determining  
364 the geographic ranges of species and the accumulation of species in the region (Fine, 2015). Previous  
365 studies aiming to explain patterns of biodiversity have focused on the current climate (Harrison et al.,  
366 2015), energy (Kreft and Jetz, 2007), soil attributions (Ulrich et al., 2014), human activities (Hautier  
367 et al., 2015; Newbold et al., 2015) or water availability (Jiao et al., 2021; Liu et al., 2021). Modern  
368 climate research on biodiversity and ecosystem functions has been widely confirmed (Walther et al.,  
369 2002; Liu et al., 2021; Yang et al., 2011), but our research shows that the pattern of biodiversity is  
370 also affected by past climates, and especially climate anomalies. Based on climate-related traits,  
371 climate anomalies filtered the regional species pool, which in turn affected contemporary  
372 biodiversity patterns.

373 Species richness is affected by the significant positive effects of AI, and the significant negative

374 effects of MAT and  $AMAT_{mid}$ . Jansson's research showed that the total number of vascular plant  
375 species decreased with increasing temperature change since the LGM in mainland areas (Jansson,  
376 2003), which is inconsistent with our results. We found that the species richness of Mongolian  
377 Plateau grassland is more affected by temperature changes since the Mid-Holocene. In Europe, the  
378 richness of widespread species was largely controlled by the modern climate, while the LGM climate  
379 and climatic heterogeneity were codominant with modern climate as controls of richness for  
380 restricted and intermediate species, which appear to still be associated with their glacial refugia  
381 (Svenning and Skov, 2007b).

382       Phylogenetic diversity (PD) is usually used to quantify the uniqueness of a region's evolution.  
383 On longer timescales, the effects of climate on speciation and extinction may cumulatively affect  
384 current PD patterns (Svenning et al., 2015). Our research showed that PD was negatively correlated  
385 with MAT and  $AMAT_{mid}$ , but not significantly related to temperature anomalies during the Last  
386 Glacial Maximum. However, the PD of global forest ecosystems is positively associated with  
387 temperature and precipitation and is negatively associated with Quaternary precipitation change  
388 (Kubota et al., 2018). This indicates the importance of paleoprecipitation variation in shaping the  
389 pattern of contemporary phylogenetic diversity in forest ecosystems, possibly by survival and  
390 recolonization from refugia along hydrological gradients (Blonder et al., 2018). Additionally,  
391 Quaternary glacial-interglacial climate oscillations led to the extinction of trees in many parts of the  
392 globe, for example in Australia (Macphail et al., 1995) and Europe (Svenning, 2003), affecting the  
393 PD of global forest ecosystems. It was shown that herbaceous plants were mainly affected by climate  
394 change since Mid-Holocene, while woody plants were mainly affected by climate change since the  
395 LGM, which may be due to the differences in morphology of herbaceous and woody plants (Liu et

396 al., 2018b; Wang et al., 2021). Woody plants with large conduits are vulnerable to drought or  
397 freezing and cause clogging of conduits (Zanne et al., 2014), and thus, were more susceptible to cold  
398 Quaternary climatic conditions. In contrast, herbs can mitigate the effects of extreme weather by  
399 producing underground buds and stems, or by wilting of aboveground parts (Qian et al., 2017).

400 Our results suggested that functional richness was negatively related to Last Glacial Maximum  
401 climate anomaly. This may be due to the intolerance of plant traits to past climatic conditions  
402 (Bhagwat and Willis, 2008) and the postglacial migration lag (Svenning et al., 2008). In the Late  
403 Quaternary, the Mongolian Plateau experienced severe alternating dry and wet climate fluctuations  
404 (Tian et al., 2017), and likely experienced a non-random removal of functional combinations and  
405 change in functional diversity (Ordonez and Svenning, 2017). Previous research has indicated that  
406 the magnitude of past glacial-to-interglacial warming was sufficient at most locations across the  
407 globe (including the Mongolian Plateau) to drive moderate to large changes in vegetation  
408 composition and structure (Nolan et al., 2018). When climate changes, inappropriate species may be  
409 quickly ruled out, and appropriate species may migrate more slowly, resulting in a negative  
410 correlation between the paleoclimate anomaly and contemporary FD in the Mongolian Plateau. This  
411 is also limited by the spreading ability or migration potential of plants after the glaciers retreated,  
412 when species with inappropriate characteristics disappeared from the community and were not  
413 replaced by other species (Blonder et al., 2018). Studies in Europe indicate that the lagging effect of  
414 glacial-interglacial climate instability on functional diversity is >10,000 years (Ordonez and  
415 Svenning, 2015).

#### 416 **4.3 Effects of climate on the relationship between biodiversity and biomass**

417 The influence of climate on relationship between contemporary diversity and biomass may be

418 caused by a combination of climate change and human activities in the Mongolian Plateau grasslands.  
419 In the eastern part of the Mongolian Plateau, the interval of 35230 to 25150 yr B.P. was a  
420 forest-steppe landscape under humid conditions, represented by Pinaceae, Compositae and  
421 Chenopodiaceae (Tian et al., 2017). Subsequently, the forest patches gradually shrank, the vegetation  
422 transitioned to the steppe landscape, and drought began to intensify. During the Last Glacial  
423 Maximum period, the vegetation types on the Mongolian Plateau were mainly polar, alpine and  
424 temperate deserts (Ray and Adams, 2001), and the main plants were Compositae and  
425 Chenopodiaceae. By the Holocene, xerophytes had declined sharply, and plants of humid climates  
426 had increased. The humidity increased during the early Holocene, and generally humid conditions  
427 lasted from 10,400 until 7000 yr BP and the region experienced the Lavliakan humid phase  
428 (Lioubimtseva, 2004; Yin et al., 2011), with more hygrophilous species, such as Cyperaceae (Tian et  
429 al., 2017). This climate condition was also conducive to the development and spread of Compositae  
430 and Gramineae families in the steppes of Central Asia (Lioubimtseva, 2004). Since approximately  
431 5200 yr BP to present, the climate has become more arid, with corresponding vegetation change and  
432 strong aeolian activity (Yin et al., 2011).

433 As far as aboveground biomass is concerned, after taking into account climatic factors, it is  
434 mainly directly affected by aridity index, while the three dimensions of biodiversity have no  
435 significant impact on it, which is consistent with our previous research (Li et al., 2020). A  
436 meta-analysis of 40 global grasslands plant communities showed that the response of plant diversity  
437 to climate warming was an important factor in determining grassland aboveground biomass (Shao et  
438 al., 2021). Similarly, paleoclimate changes also have no direct effects on aboveground biomass,  
439 which indirectly affects aboveground biomass through regulating biodiversity. This is mainly

440 because paleoclimatic filtering can alter the historical legacies of species and functional diversity  
441 (removal or accumulation over time of species and functional states) through evolution, extinction,  
442 or recolonization (Svenning et al., 2015). Legacies in the species and functional traits pool further  
443 affect ecosystem function, leading to changes in biomass (Svenning et al., 2015).

444 In addition, the relationship between biodiversity and biomass is also affected by human  
445 activities (Buisson et al., 2022). Human history has become profoundly intertwined with grassland  
446 communities, from the evolution of the *Homo* in savannas 2 million years ago to the emergence of  
447 species domestication in agricultural societies 10,000 years ago (Strömberg and Staver, 2022).  
448 Palaeoecological and archaeological evidence shows that people have shaped most of terrestrial  
449 nature for at least 12,000 years, including burning, hunting, cultivation and domestication (Ellis et al.,  
450 2021). In the Mongolian Plateau, especially in the Inner Mongolia region of northern China, grazing  
451 appeared at ~5.7–5.5 ka B.P. and further intensified again after ~4.2–4.0 ka B.P. (Huang et al., 2021).  
452 A large number of studies have shown that the intensification of grazing activities also causes  
453 changes in biodiversity and biomass (Liang et al., 2021; Herrero-Járegui and Oesterheld, 2018;  
454 D íaz et al., 2007). Therefore, there is an urgent need for future research to develop systematic  
455 analytical frameworks to assess the importance of paleoclimate and climate change in shaping  
456 contemporary biodiversity and ecosystems, particularly under the influence of human activities.

## 457 **5. Conclusion**

458 We conclude that unique evolutionary and ecological histories played key roles in explaining  
459 biodiversity patterns in the Mongolian Plateau. When climatic conditions are not considered,  
460 taxonomic diversity, phylogenetic diversity and functional diversity all have effects on community  
461 biomass, and taxonomic diversity has a more obvious impact on biomass. However, the climate after

462 the Last Glacial Maximum has left a strong legacy affecting contemporary biodiversity patterns.  
463 These findings extend our understanding of the spatial and temporal scale of climate effects on  
464 biodiversity and aboveground biomass, providing additional confidence that the paleoclimate had a  
465 key role in shaping contemporary biodiversity patterns.

466

#### 467 **Authors' Contributions**

468 Z. Li analyzed the data and wrote the first draft of the manuscript. Zh. Li, J. Zhang, G. Han, F.Y. Li  
469 and C. Liang contributed to later versions of the manuscript and all authors provided constructive  
470 comments to improve the manuscript. F.Y. Li and C. Liang designed and led the field survey. Z. Li,  
471 Zh. Li, X. Tong, J. Zhang, L. Dong, Y. Zheng, B. Miao, W. Ma, L. Zhao, L. Wang, L. Wen, C. Liang  
472 and F.Y. Li conducted the experiment and collected the data.

#### 473 **Data available**

474 The data that support the findings of this study are available on request from the corresponding  
475 author.

#### 476 **Conflict of interest statement**

477 The authors declare that they have no conflict of interest.
