20 **Abstract**

21 During the Late Pleistocene, stadial and interstadial fluctuations affected vegetation, fauna, and human
22 groups that were forced to cope with these pronounced ~~spatial-and-temporal~~ climatic and environmental
23 changes ~~in time and space~~. These changes were especially abrupt during the Marine Isotopic Stage (MIS)
24 3. ~~However, little is still known about the local and regional climatic conditions experienced by hominins in~~
25 ~~Europe.~~ Here, we reconstruct the climatic trends in northern Iberia considering the stable isotopic
26 composition of ungulate skeletal tissues found in archaeological deposits dated between 80 to 15 ~~ka-000~~
27 cal BP. The carbon and oxygen isotopic composition preserved in the carbonate fraction of tooth enamel
28 provides a reliable and high-resolution proxy of the food and water consumed by these animals, which is
29 indirectly related to the local vegetation, environment, and climate, allowing us to estimate
30 paleotemperatures and rainfall ~~data~~ intensity. This study presents ~~new isotope data from~~ 44 bovine, equid,
31 and cervid teeth from five archaeological sites in the Vasco-Cantabrian region (El Castillo, ~~El Otero~~, Axlor,
32 Labeko Koba, Aitzbitarte III ~~interior and El Otero~~.) and one in ~~the Mediterranean area~~ northeastern Iberia
33 (Canyars), where human evidence is attested from the Mousterian to the Magdalenian. The carbon isotope
34 values reflect animals feeding on ~~diverse~~ C3 plants ~~with a mix-feeder diet mainly developed~~ in open
35 environments, ~~and point to.~~ However, ~~carbon isotope value ranges point to~~ differentiated ecological niches
36 for equids and bovines, especially during the Aurignacian in the Vasco-Cantabrian region. Temperature
37 estimations based on oxygen isotopic compositions and rainfall obtained from carbon isotopic compositions
38 indicate colder and more arid conditions than nowadays from the Late Mousterian to the Aurignacian. The
39 contemporary ~~Mediterranean-northeastern Iberia~~ site shows slightly lower temperatures related to an arid
40 period when animals mainly graze in open landscapes. In the Vasco-Cantabrian region, during the MIS2,
41 the Gravettian data reflect a landscape opening, whereas the Magdalenian points to warmer ~~conditions~~ (but
42 still arid) ~~conditions~~.

44 1. Introduction

45 Understanding the local and regional climatic ~~evolution-variability~~ during the Late Pleistocene in southern
46 Europe is crucial for assessing the potential impact of climate on the adaptation and decline of Neanderthals,
47 ~~as well as~~ the subsequent expansion and resilience of Anatomically Modern Humans during the Upper
48 Paleolithic (e.g., D'Errico and Sánchez Goñi, 2003; Finlayson and Carrión, 2007; Sepulchre et al., 2007;
49 Staubwasser et al., 2018). During the Late Pleistocene, the climatic records demonstrate stadial and
50 interstadial continuous fluctuations during the Marine Isotope Stage 3 (MIS 3, ca. 60-27 ka) and MIS 2 (ca.
51 27-11 ka). Human groups had to face those episodes, which affected ~~different~~ vegetation and fauna ~~to~~
52 ~~different extents~~, depending on the region. Northern Iberia is a key study area due to the abundance of well-
53 preserved archaeological caves and rock shelters where, in the last decade, an updated and
54 multidisciplinary approach has been applied to disentangle how changing environmental conditions affected
55 the subsistence dynamics of Middle and Upper Paleolithic hominins. Recent chronological, technological,
56 ~~and~~ subsistence studies ~~and~~ ecological reconstructions are revealing a ~~wider regional circumstance~~ more
57 complex ~~regional panorama~~ than previously known (e.g., Sánchez Goñi, 2020; Vidal-Cordasco et al., 2022;
58 ~~2023~~; Timmermann, 2020; Klein et al., 2023).

Formatted: Italian (Italy)

59 The Vasco-Cantabrian region, located in northwestern Iberia, is subject to the influence of Atlantic climatic
60 conditions, ~~and has where been widely recently has been evaluated debated as a region that was~~
61 ~~significantly~~ impacted ~~of-by~~ the glacial-interglacial oscillations during ~~the~~ MIS3 (Vidal-Cordasco et al.,
62 2022). Modelling of traditional environmental proxies (small vertebrates and pollen) from archaeo-
63 paleontological deposits show a progressive shift in the climatic conditions with decreasing temperatures
64 and rainfall levels detected during the late Mousterian (Fernández-García et al., 2023). Ecological alterations
65 have been observed in large mammals, such as niche partitioning between horses and cervids (Jones et
66 al., 2018), a decrease in the available biomass for secondary consumers, and consequently, ~~a decrease~~
67 ~~reduction in the ungulate herbivores~~ carrying capacity ~~with regards to ungulates~~ (Jones et al., 2018; Vidal-
68 Cordasco et al., 2022). Cold and arid conditions are maintained during the Aurignacian and the Gravettian
69 until the onset of MIS2. Afterwards, during the Last Glacial Maximum (LGM, 23-19 ka), the global climatic
70 deterioration associated with this glacial phase results in colder and more arid conditions in the region, with
71 a predominance of open landscapes. However, this region still provided resources for human ~~exploitation~~
72 survival acting as a refugia ~~area~~ with more humid conditions in comparison to the Mediterranean area
73 (Cascalheira et al., 2021; Garcia-Ibaibarriaga et al., 2019a; Lécuyer et al., 2021; Fernández-García et al.,
74 2023; Fagoaga, 2014; Posth et al., 2023). By the end of the LGM, a climate amelioration and a moderate
75 expansion of the deciduous forest are documented from the late Solutrean through the Magdalenian (Jones
76 et al., 2021; Garcia-Ibaibarriaga et al., 2019a).

77 In contrast, northeastern Iberia is influenced by the Mediterranean climate. During MIS 3, ~~this period in~~
78 ~~temperatures in this region has frequently been described as is often were characterised as being cooler by~~
79 ~~colder temperatures and with, and with higher rainfall, higher rainfall~~ compared to the present, ~~but and~~
80 ~~less with climatic fluctuations described as being less~~ pronounced ~~climatic fluctuations when~~ compared to
81 the Vasco-Cantabrian region ~~in the same period~~ (López-García et al., 2014; Fernández-García et al., 2020;
82 Vidal-Cordasco et al., 2022). ~~Archaeobotanical and small vertebrate evidence Small vertebrate communities~~
83 ~~and archaeobotanical evidence~~ indicate relatively stable climatic conditions, but also ~~suggest~~ the
84 persistence of open forests during the Middle to Upper Paleolithic transition, as ~~found~~ in northwestern Iberia
85 (Allué et al., 2018; Ochando et al., 2021). However, certain records indicate specific climatic
86 ~~excursions episodes~~, such as increased aridity and landscape opening during Heinrich Events 4 and 5 (e.g.,
87 Álvarez-Lao et al., 2017; Daura et al., 2013; López-García et al., 2022; Rufi et al., 2018).

88 ~~These multi-proxy studies have significantly expanded our understanding of the environmental evolution in~~
89 ~~Iberia, alongside proxies derived from marine core records in Iberia margins~~ (Naughton et al., 2007;
90 Roucoux et al., 2001; Sánchez-Goñi et al., 1999, 2009; Martrat et al., 2004; Fourcade et al., 2022) ~~and other~~
91 ~~regional paleoclimatic records sourced from local natural deposits~~ (e.g., Pérez-Mejías et al., 2019; Moreno
92 et al., 2010, 2012; González-Sampérez et al., 2020; Ballesteros et al., 2020) ~~thereby providing a valuable~~

Formatted: Spanish (Spain)

93 ~~framework for understanding environmental evolution. However, the availability of proxies enabling the~~
94 ~~establishment of direct connections between these environmental shifts and human activities remains~~
95 ~~limited.~~

96
97 ~~These While multi-proxy studies have significantly expanded our understanding of the environment in Iberia.~~
98 ~~However, there is still limited availability of high resolution proxies directly linked directly to human activity.~~
99 In this study, we ~~propose to~~ investigate the ~~palaeoecological~~ and ~~palaeo~~environmental dynamics of ~~past~~
100 ~~ungulates of this region in northern Iberia~~ during the late Middle and Upper Paleolithic by measuring the
101 carbon and oxygen isotopic composition ($\delta^{13}\text{C}$, $\delta^{18}\text{O}$) of bioapatite carbonates ($\delta^{13}\text{C}_{\text{carb}}/\delta^{18}\text{O}_{\text{carb}}$) preserved
102 in archaeological mammal teeth. ~~These analyses provide high-resolution snapshots of ecological~~
103 ~~information from animals accumulated during human occupations at the cavsites.~~ Tooth enamel forms
104 incrementally and does not biologically remodel (Passey and Cerling, 2002; Kohn, 2004), in contrast to other
105 ~~body~~ tissues such as bone, which implies that the isotope values measured on them reflect the animal
106 diet and water sources consumed during its mineralisation, around one to two years of ~~animal life in our~~
107 ~~study species life for the species included in our study (bovids, equids, cervids) (e.g., Hoppe et al., 2004;~~
108 ~~Pederzani and Britton, 2019; Ambrose and Norr, 1993; Luz et al., 1984).~~ ~~The preserved carbon and oxygen~~
109 ~~isotope composition in the carbonate fraction of tooth enamel offers a high resolution record of the dietary~~
110 ~~choices of the plants and water animals consume, which indirectly reflects the vegetation, environmental~~
111 ~~conditions, and climate. The preserved carbon isotope composition rely on dietary choices of animals~~
112 ~~reflecting mainly the type of plant consumed (C3/C4), exposition to light and levels of humidities on animal~~
113 ~~dietary choices reflecting mainly the type of plant consumed (C3/C4), exposition to light and humidity levels.~~
114 ~~Otherwise, the oxygen isotope composition reflects mainly the environmental water consumed by animals,~~
115 ~~directly by drinking or through diet, which reflects isotopic information derived from water sources as well as~~
116 ~~changes in climatic conditions. Both indirectly provide information on the vegetation and climate that This~~
117 ~~allows us to estimate~~ past temperatures, rainfall, and moisture ~~levels~~ on a sub-annual scale, returning
118 isotopic ~~information data~~ of the foraging areas where animals were feeding during ~~teeth teeth~~ formation.

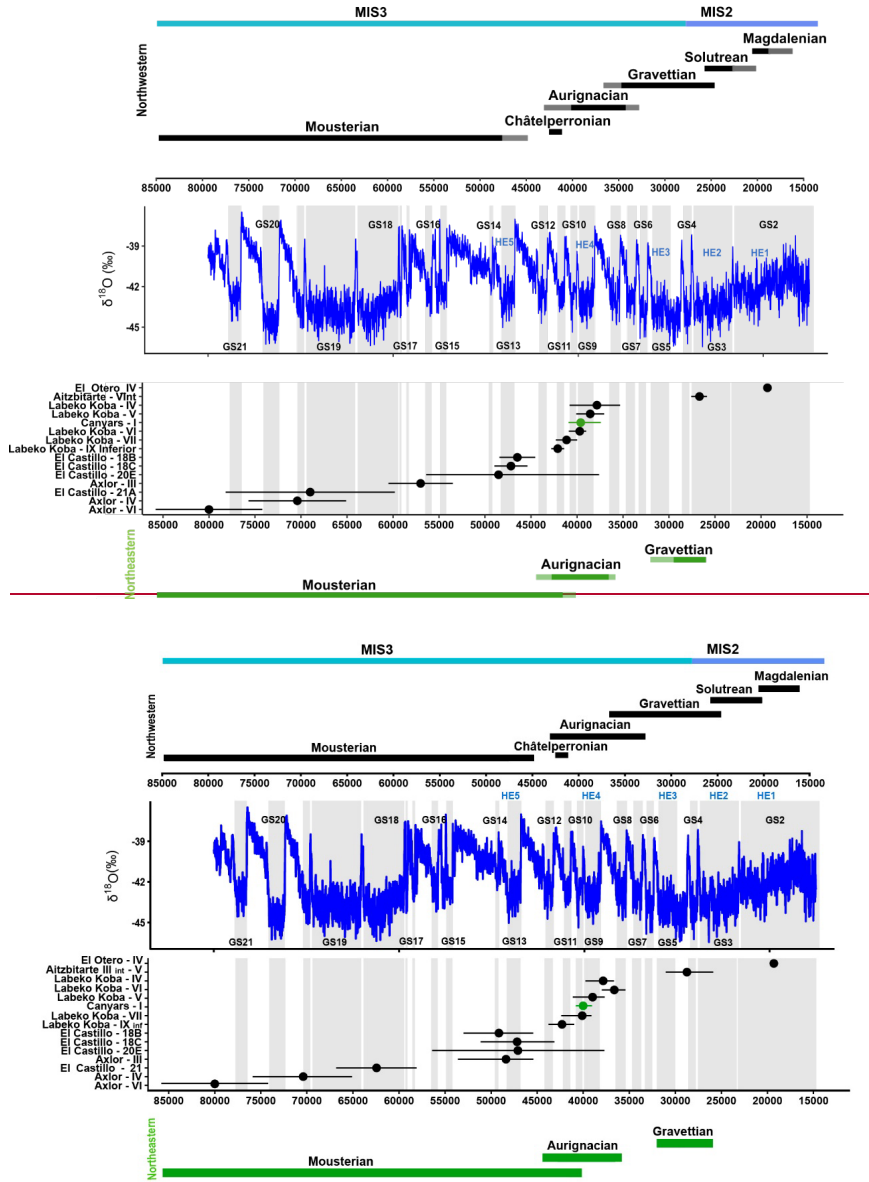

119 By analysing the stable isotopic composition of 44 ungulate teeth obtained from 15 archaeological levels
120 ~~directly~~ associated with human occupation, including El Castillo, ~~El Otero~~, Axlor, Labeko Koba, Aitzbitarte
121 ~~III interior and El Otero~~ in northwestern Iberia, and Terrasses de la Riera dels Canyars in northeastern Iberia,
122 this study presents novel insights into local and regional environmental and climatic trends during the Late
123 Pleistocene (Fig.1; Fig.2; Appendix A). Specifically, it focuses on the Middle to Upper Paleolithic transition
124 in both areas and the post-LGM period in the Vasco-Cantabrian region.

125 The main objectives of this work are: 1) to assess how regional environmental conditions, including changes
126 in moisture and vegetation cover, but also temperatures and rainfall, are recorded ~~in tooth enamel in the~~
127 stable isotopic composition ~~of tooth enamel~~; 2) to ~~approach characterize~~ animal diet and their ecological
128 niches; 3) to obtain quantitative temperature data to compare with available proxies; 4) to characterise
129 seasonal patterns of animals found in the archaeological sites by identifying winter and summer fluctuations.
130 The chronological ~~resolution information in associated to the study studied areas levels for this period~~ allows
131 us to ~~cor~~relate regional paleoenvironmental changes with global records.

2. Archaeological sites and sampled material

This study selected a total of 44 ungulate teeth including 25 bovines (*Bos primigenius*, *Bison priscus*, *Bos/Bison* sp.), 14 equids (*Equus* sp. and *Equus ferus*), and ~~five~~ cervids (*Cervus elaphus*) ~~found~~ ~~in~~ ~~originating from~~ five archaeological sites in the Vasco-Cantabrian region (El Castillo, El Otero, Axlor, Labeko Koba, Aitzbitarte III ~~interior~~) and one in the Mediterranean area (Terrasses de la Riera dels Canyars, henceforth Canyars). These teeth were recovered from 15 archaeological levels attributed to the following technocomplexes: Mousterian (n=14), Transitional Aurignacian (n=10), Châtelperronian (n=2), Aurignacian (n=12), Gravettian (n=1) and Magdalenian (n=5) (Table 1 and 2, ~~Appendix B~~). Archaeozoological studies of the archaeological sites are available (synthesis in Marin-Arroyo and Sanz-Royo, 2022; Daura et al., 2013) and most prove that faunal remains were accumulated by human acquisition during the different cultural phases. ~~The isotopic results of equids from El Castillo~~ [The isotopic results of equids teeth and other ungulates bone collagen from El Castillo](#) were previously published by Jones et al. (2019) in combination with the ~~bone collagen~~ stable isotopes of ~~in~~ ungulate ~~prey capture at s~~ from the site, as well as ~~the combined~~ bioapatite ~~carbonate and~~ phosphate analyses of bovines from Axlor (Pederzani et al., 2023). [Single radiocarbon dates for each site were calibrated using OxCal4.4 software](#) (Ramsey, 2009), [considering the INTCAL20 calibration curve](#) (Reimer et al., 2020). [Dates provided represent an approximate age for each level where ungulate remains were recovered, incorporating either multiple dates or a single date. For sites with multiple various dates, Bayesian chronology modeling was performed using OxCal4.4. A comprehensive description of each archaeological site is provided in Appendix A, while further details on dating methods and selected dates for each level can be found in Appendix B.](#)

3. Methods

3.1 Tooth sampling

All teeth included were sequentially sampled to reconstruct the complete $\delta^{18}\text{O}_{\text{carb}}$ and $\delta^{13}\text{C}_{\text{carb}}$ intratooth profiles based on enamel carbonate bioapatite. Intratooth sequential sampling was applied to the second and third molars and third and fourth premolars. Bovine and horse teeth sampled exceeded 3-4 cm of crown height to ensure that at least a one-year isotopic record of animal life was obtained (Hoppe et al., 2004; Britton et al., 2019). Samples were taken perpendicular to the growth axis on the tooth where the enamel was best preserved, avoiding, whenever possible taphonomic alterations such as cracks or postdepositional damages. Samples were performed in the ~~labial-buccal~~ face for the lower teeth and the lingual part for the upper ones. The outermost enamel surface was abraded to remove the superficial enamel, calculus, cementum, or concretions adhering to the surface to avoid contaminations. The sequential sampling consisted of straight strips (ca. 8 x 1.5 x 1 mm) covering the width of the selected lobe, approximately every 2-3 mm, from the crown to the Enamel-Root-Junction (ERJ). The sample depth covered around 75% of the enamel depth, and dentine inclusion was avoided. A low-revolution variable-speed manual drill was used, equipped with 1 mm diamond-coated drill bits of conical and cylindrical shape. About 10-15mg of enamel powder was collected in each subsample, generating 693 subsamples for IRMS measurements (see complete intratooth profiles in Appendix C).

183

184 3.2 Sample treatment and stable isotope mass spectrometry

185 Several authors have debated the necessity of chemical pre-treatments to remove organic matter and
186 secondary carbonates from bioapatite carbonates before stable isotopic analysis. Some chemical
187 treatments can introduce secondary carbonates, increase carbonate content, and alter the original isotopic
188 signal (Snoeck and Pellegrini, 2015; Pellegrini and Snoeck, 2016). The "side effects" of these pre-treatments
189 can compromise the final isotopic signal measured. For this reason, in this work, most of the samples were
190 not pretreated, except for the equids and cervids samples from Labeko Koba, and Aitzbitarte III interior, and
191 the cervids and equids from El Otero and El Castillo that were sampled and pretreated in the context of the
192 initial project in an earlier phase of the project. The absence of pretreatment can elevate the risk of secondary
193 carbonates (France et al., 2020; Chesson et al., 2021). Nonetheless, any pretreatment method cannot
194 guarantee their complete removal, and the 'side effects' may compromise the final isotopic signal to a greater
195 extent. While variations in pretreatment methods exist among samples in this study, the lack of a universally
196 accepted protocol necessitates careful consideration of any potential isotopic effects resulting from these
197 differences.

198 Pretreatment was followed for above-mentioned samples of this work from fourteen teeth was established by
199 Balasse et al. (2002), where around 7 mg of powdered enamel was prepared and pretreated with 3% of

200 sodium hypochlorite (NaOCl) at room temperature for 24 h (0.1 ml/mg sample); and thoroughly rinsed with
201 deionised water, before a reaction with 0.1M acetic acid for 4 h (0.1 ml/mg sample) (Balasse et al., 2002;
202 equivalent protocol in Jones et al., 2019). Samples were then thoroughly rinsed, frozen, and freeze-dried.
203 NaOCl is one of the most common agents used for pretreating carbonates and works as a base that removes
204 organic matter by oxidation. Although it is considered one of the most efficient agents for removing organic
205 matter, it can induce the absorption of exogenous carbonates, such as atmospheric CO₂ and secondary
206 carbonates (Snoeck and Pellegrini, 2015; Pellegrini and Snoeck, 2016). It is argued that using acetic acid
207 after NaOCl pretreatment can remove exogenous carbonates absorbed during NaOCl application. However,
208 it is unclear if all newly introduced carbonates are finally released and which effect they produce on the
209 original isotopic composition. ~~While variations in pretreatment methods exist among samples in this study,~~
210 ~~the lack of a universally accepted protocol necessitates careful consideration of any potential isotopic effects~~
211 ~~resulting from these differences.~~ These samples were analysed in the Godwin Laboratory (Department of
212 Earth Sciences, University of Cambridge). Enamel powder samples were reacted with 100%
213 orthophosphoric acid for 2 h at 70°C in individual vessels in an automated Gasbench interfaced with a
214 Thermo Finnigan MAT253 isotope ratio mass spectrometer. Results were reported in reference to the
215 international standard VPDB and calibrated using the NBS-19 standard (limestone, $\delta^{13}\text{C} = +1.95\text{‰}$ and $\delta^{18}\text{O}$
216 $= -2.2\text{‰}$; Coplen, 2011) for which the precision is better than 0.08‰ for $\delta^{13}\text{C}$ and 0.11‰ for $\delta^{18}\text{O}$.

217 For the non-pre-treated samples, carbon and oxygen stable isotopic ratios were measured using continuous
218 flow-isotope ratio mass spectrometry, specifically a Europa Scientific 20-20 IRMS coupled to a
219 chromatograph, at the Iso-Analytical laboratory in Cheshire, UK. The samples were weighed into clean
220 exetainer tubes after being flushed with 99.995% helium. Phosphoric acid was then added to the samples,
221 and they were allowed to react overnight to ensure the complete conversion of carbonate to CO₂, following
222 the method outlined by Coplen et al. (1983). The reference materials used for VPDB calibration and quality
223 control of the analysis included: IA-R022 (calcium carbonate, $\delta^{13}\text{C} = -28.63\text{‰}$, $\delta^{18}\text{O} = -22.69\text{‰}$), NBS-18
224 (carbonatite, $\delta^{13}\text{C} = -5.01\text{‰}$, $\delta^{18}\text{O} = -23.2\text{‰}$), IA-R066 (chalk, $\delta^{13}\text{C} = +2.33\text{‰}$; $\delta^{18}\text{O} = -1.52$). The accepted
225 values of the in-house standards IA-R022 and IA-R066 were obtained by calibrating against IAEA
226 international reference materials, NBS-18 and NBS-19, and NBS-18 and IAEA-CO-1 (Carrara marble, $\delta^{13}\text{C}$
227 $= 2.5\text{‰}$, and $\delta^{18}\text{O} = -2.4\text{‰}$), respectively. Additionally, in-house standards long-term measured were used:
228 ILC1 (calcite, $\delta^{13}\text{C} = 2.13$, $\delta^{18}\text{O} = -3.99\text{‰}$), and Y-02 (calcite, $\delta^{13}\text{C} = 1.48$, $\delta^{18}\text{O} = -9.59\text{‰}$). The analytical
229 precision of quality control standard replicates was better than 0.09‰ for $\delta^{13}\text{C}$ and better than 0.12‰ for
230 $\delta^{18}\text{O}$. ~~The calcium carbonate content test on of these samples, ranging between 3.9% and 8.9%, does~~
231 ~~not indicate a substantial presence of secondary carbonates, considering (Chesson et al. (2021).~~
232 ~~Additionally, phosphate results on samples from Axlor showed $\delta^{18}\text{O}_{\text{carb}} - \delta^{18}\text{O}_{\text{phos}}$ offsets within the expected~~
233 ~~range for well-preserved samples (Pederzani et al., 2023).~~

234 3.3 Carbon stable isotopic compositions as environmental and ecological tracers

235 To unravel animal diet and to compare the different species, in standardised terms, it is necessary to
236 consider the fractionation-enrichment factor (ϵ^*) between $\delta^{13}\text{C}$ obtained by the animal on its diet ($\delta^{13}\text{C}_{\text{diet}}$)
237 and $\delta^{13}\text{C}$ recorded on enamel carbonates ($\delta^{13}\text{C}_{\text{carb}}$) (Bocherens, 2003; Cerling and Harris, 1999). The ϵ^*
238 estimated for large ruminant mammals results in an offset of around 14.1‰ between diet and dental enamel,
239 which is commonly applied generally commonly applied to medium-sized herbivores. However, it is well-
240 known that this offset varies between species, considering animals' different physiological parameters.
241 Recently, a formal model to predict species-specific diet-consumer isotopic offsets has been proposed,
242 which uses body mass (BM) and digestive physiology as the main factors that regulating-regulate the ϵ^*
243 (Tejada-Lara et al., 2018). This model proposes the following prediction equations for ruminant or foregut
244 fermenters (Equation 1: Eq.1) and hindgut fermenters (Eq. 2):-

Formatted: Subscript

Formatted: Subscript

245 (Eq. 1) $\epsilon^* = 2.34 + 0.05 \text{ (BM)}$ $[r^2=0.78; \text{p-value}=0.008]$

246 (Eq. 2) $\epsilon^* = 2.42 + 0.032 \text{ (BM)}$ $[r^2=0.74; \text{p-value}=0.003]$

247 ~~In this work, we compare~~ This work compares species with different digestive physiology, ruminants for
248 bovines and cervids, and non-ruminants for equids. The ϵ^* value was adjusted ~~to~~ for each animal to avoid
249 bias from digestive physiology when comparing these species. The following ~~fractionation enrichment~~
250 factors have been used: 14.6‰ for *Bos taurus* (Passey et al., 2005a), 13.7‰ for *Equus caballus* (Cerling
251 and Harris, 1999), and 13.2‰ for *Cervus elaphus* (Merceron et al. (2021) following (Eq. 1) for ruminants
252 with a mean body mass of 125 kg.

253 ~~In body tissues, carbon~~ isotopic composition ~~in body tissues~~ is considered a combination of diet
254 (understood as consumed food), environment openness (and associated exposure to light), and the amount
255 of precipitation. ~~Assuming that $\delta^{13}\text{C}$ of past vegetation is close to $\delta^{13}\text{C}_{\text{diet}}$ of ungulates. Having the~~
256 ~~precipitation in mind,~~ Lécuyer et al. (2021) proposed to estimate Mean Annual Precipitations (MAP) from
257 $\delta^{13}\text{C}_{\text{carb}}$ ~~preserved in enamel carbonates~~, derived from diets based on C3 plants. After transforming ~~$\delta^{13}\text{C}$~~
258 ~~from enamel carbonate ($\delta^{13}\text{C}_{\text{carb}}$) to $\delta^{13}\text{C}$ of the diet ($\delta^{13}\text{C}_{\text{diet}}$)~~ using the ~~fractionation enrichment~~ factors
259 established above, this work suggested transforming this value to $\delta^{13}\text{C}$ from vegetation ($\delta^{13}\text{C}_{\text{leaf}}$). ~~However,~~
260 ~~the isotopic composition of animals' diet may not directly reflect vegetation cover, but rather the food~~
261 ~~preference of the animal and this approach should be discussed alongside other environmental data.~~

262 The MAP estimation is based on least square regression developed by Rey et al. (2013) and based on Kohn
263 (2010) dataset (Eq.4), which requires first to estimate the $\delta^{13}\text{C}_{\text{leaf}}$ (Eq. 3). The $\delta^{13}\text{C}$ values of atmospheric
264 CO_2 ($\delta^{13}\text{C}_{\text{atm}}$) are fixed in -7‰ (Lécuyer et al., 2021; Leuenberger et al., 1992; Schmitt et al., 2012).
265 ~~Atmospheric CO_2 levels have varied throughout the Late Pleistocene, with $\delta^{13}\text{C}_{\text{atm}}$ range between -7 to -~~
266 ~~6.4‰ (Eggleston et al., 2016), favouring an age-specific correction approach. However, maintaining general~~
267 ~~corrections is preferred considering the chronological uncertainty of the studied levels.~~

268 (Eq.3) $\delta^{13}\text{C}_{\text{leaf}} \text{ (VPDB)} = (\delta^{13}\text{C}_{\text{atm}} - \delta^{13}\text{C}_{\text{diet}}) / [1 + (\delta^{13}\text{C}_{\text{diet}} / 1000)]$

269
270 (Eq.4) $\text{Log}_1(\text{MAP}+300) = 0.092(\pm 0.004) \times \delta^{13}\text{C}_{\text{leaf}} + 1.148(\pm 0.074)$

271
272 ~~Additionally, The~~ Lécuyer et al. (2021) equation ~~also incorporates accounts for the consideration of~~ the pCO_2
273 effect on $\delta^{13}\text{C}_{\text{leaf}}$ estimation, which is expected to result in an offset of +1‰ from current levels (considering
274 that pCO_2 was ~~180 ppm during the LGM, which is lower than that~~ 300ppm experienced during the ~~post~~
275 ~~post-after the deglaciation period around 15 ka). If this correction was not applied, MAP results will could~~
276 be underestimated by -150mm. ~~In agreement with Lécuyer et al. (2021) appreciation, these MAP estimations~~
277 ~~are a preliminary approximation and should be cross-validated with other environmental proxies. The~~
278 ~~associated uncertainties range from ± 100 to 200 mm, influencing the interpretation of the final values.~~

279

280

281 3.4 Oxygen stable isotope compositions as environmental tracers

282 Intratooth profiles are known to provide a time averaged signal compared to the input isotopic signal ($\delta^{13}\text{C}/$
283 ~~$\delta^{18}\text{O}_{\text{carb}}$) during enamel formation (Passey et al., 2005b). This signal attenuation is caused both by time~~
284 ~~averaging effects incurred through the extended nature of amelogenesis and tooth formation, and through~~
285 ~~the sampling strategy. During mineralisation, the maturation zone, which is time averaged, often affects a~~
286 ~~large portion of the crown height and might affect the temporal resolution of the input signal of the sample~~
287 ~~taken. To obtain climatically informative seasonal information on the analysed teeth, the application of the~~

Formatted: Subscript

288 inverse modelling method proposed by (Passey et al., 2005b) is, therefore, required ~~applied in this work.~~
289 This method allows us to computationally estimate the time averaging effects of sampling and tooth
290 formation to obtain more accurately the original amplitude of the isotopic input signal, ~~thus the original~~
291 ~~amplitude of the isotopic input signal more accurately, thus, to summer and winter extremes (Appendix D).~~
292 This method considers parameters based on the amelogenesis trends of each species and sampling
293 geometry, which are critical for a meaningful interpretation of intratooth isotope profiles. To evaluate the
294 data's reproducibility and precision, the model also estimates the error derived from the uncertainty of the
295 sampling and the mass spectrometer measurements ~~the model also estimates the error derived from the~~
296 ~~sampling uncertainty and the mass spectrometer measurements to evaluate the data's reproducibility and~~
297 ~~precision.~~ This method was initially developed for continuously growing teeth, taking into account a constant
298 growth rate within a linear maturation model, which ~~with a progressive time average increment as sampling~~
299 ~~advances along the tooth profile. The species studied in this research exhibit non linear tooth enamel~~
300 ~~formation, particularly in later forming molars (Bendrey et al., 2015; Zazzo et al., 2012; Passey and Cerling,~~
301 ~~2002; Kohn, 2004; Blumenthal et al., 2014). Although the aforementioned model~~ ~~model mentioned above is~~
302 ~~not ideal, as it does not account for non linear enamel formation and certain growth parameters for the~~
303 ~~species included are unknown, it is the best estimation based on the current state of the field and remains~~
304 ~~widely used (Pederzani et al., 2023, 2021a, b). Flat and less sinusoidal profiles are less suitable for the~~
305 ~~application of the model, given its inherent assumption of an approximately sinusoidal form. Therefore, we~~
306 ~~chose not to apply this methodology in the analysis of intratooth $\delta^{13}\text{C}$ profiles, and it is recommended to~~
307 ~~approach the interpretation of model outcomes for non sinusoidal $\delta^{18}\text{O}$ curves with caution. Further details~~
308 ~~on the application of this method can be found in Appendix D.~~

Formatted: Superscript

309 Stable oxygen isotopes from meteoric water (mainly derived from rainfall) ~~have a strong relationship~~ ~~strongly~~
310 ~~correlate~~ with mean air temperatures in mid to high latitudes (Rozanski et al., 1992; Dansgaard, 1964) on a
311 regional-to-local scale. Obligate drinkers, ~~such as like~~ bovines and horses, acquire this water and record its
312 isotopic composition in their teeth and bones with a fixed, but species-specific offset (Pederzani and Britton,
313 2019). Considering this two-step relationship, past climatic conditions can be estimated. However, most of
314 the temperature reconstructions based on $\delta^{18}\text{O}$ have considered the $\delta^{18}\text{O}$ from the phosphate fraction of
315 bioapatite enamel ($\delta^{18}\text{O}_{\text{phos}}$) to build linear correlations between tooth enamel and drinking water $\delta^{18}\text{O}$ and
316 obtain climatic information. For this reason, the $\delta^{18}\text{O}_{\text{carb}}$ ~~from carbonates~~ values obtained in this work
317 ($\delta^{18}\text{O}_{\text{carb}}$) were converted into $\delta^{18}\text{O}_{\text{phos}}$ ~~from phosphates~~ ($\delta^{18}\text{O}_{\text{phos}}$). To do so, first, to express in VSMOW
318 notation, the $\delta^{18}\text{O}_{\text{carb}}$ was corrected using the following correlation (Coplen et al., 1983; Brand et al., 2014):

$$319 \quad (\text{Eq.5}) \delta^{18}\text{O}_{\text{carb}} (\text{VSMOW}) = 1.0309 \times \delta^{18}\text{O}_{\text{carb}} (\text{VPDB}) + 30.91$$

320 Second, considering the relationship existent in tooth enamel between the carbonate and phosphate fraction
321 (Iacumin et al., 1996; Pellegrini et al., 2011), from a compilation of the existent bibliography of modern
322 animals measurements (Trayler and Kohn, 2017; Pellegrini et al., 2011; Bryant et al., 1996), Pederzani et
323 al. (2023) proposed the following correlation:

$$324 \quad (\text{Eq.6}) \delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) = 0.941 \times \delta^{18}\text{O}_{\text{carb}} (\text{VSMOW}) - 7.16$$

325 Once the isotopic information is expressed in $\delta^{18}\text{O}_{\text{phos}}$ (VSMOW), we can estimate the $\delta^{18}\text{O}$ on meteoric
326 waters ($\delta^{18}\text{O}_{\text{mw}}$). It is known that different physiological factors will condition how oxygen isotope composition
327 is fixed in each mammalian group. Thus, ~~usually,~~ the correlations ~~are~~ ~~usually~~ species-specific and
328 developed considering the ~~particular~~ physiology of each animal group. The correlation employed by this
329 work relies on recent data compilations (Pederzani et al., 2021b, 2023). In the case of horses (Eq. 7), it has
330 been considered the data combination of Blumenthal et al. (2019); Chillón et al. (1994); Bryant et al., 1994;
331 Delgado Huertas et al., 1995), whereas for bovines (Eq. 8) the data from D'Angela and Longinelli (1990)

332 and Hoppe (2006) have been put together in Eq. 4. To estimate $\delta^{18}\text{O}_{\text{mw}}$ from red deer remains, we selected
333 D'Angela and Longinelli (1990) correlation (Eq. 9):

334 (Eq.7) $\delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 22.14) / 0.6287$

335 (Eq.8) $\delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 22.436) / 0.785$

336 (Eq.9) $\delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 24.39) / 0.91$

337 Finally, paleotemperatures estimations from $\delta^{18}\text{O}_{\text{mw}}$ are typically approached using a geographically
338 adjusted linear regression, which can vary from precise adjustments (aimed at reducing errors) to broader
339 geographical adjustments that encompass more variability and but also introduce greater more significant
340 uncertainty but are less precise (e.g., Pryor et al., 2014; Skrzypek et al., 2011; Tütken et al., 2007). ~~the mean~~
341 annual temperatures (MAT) were calculated from $\delta^{18}\text{O}_{\text{mw}}$. In this work, temperatures were calculated
342 considering the linear regression model relating $\delta^{18}\text{O}_{\text{mw}}$ and air temperatures from Iberia proposed by
343 Pederzani et al. (2021), Fernández-García et al. (2019). ~~This correlation is based on monthly climatic~~
344 records (monthly mean $\delta^{18}\text{O}_{\text{mw}}$ and monthly mean air temperatures), from Western, Southern and Central
345 Europe all Iberian stations from the Global Network of Isotopes in Precipitation, operated by the International
346 Atomic Energy Association and the World Meteorological Organization (IAEA/ WMO, 2018/2020).
347 Considering current IAEA data sets from northern Iberia, there is a strong positive relationship between
348 $\delta^{18}\text{O}_{\text{mw}}$ and annual or monthly temperatures (Moreno et al., 2021). However, it is known that Iberia is
349 under a mixed influence between Atlantic and Mediterranean moisture sources that affects the isotopic
350 composition of rainfall (Moreno et al., 2021; Araguas-Araguas and Diaz Teijeiro, 2005; García-Alix et al.,
351 2021). Given uncertainties in past atmospheric circulation patterns and the limited availability of reference
352 stations, it was deemed most appropriate to select an equation that extends beyond the borders of Iberia
353 and incorporates higher variability. Different correlations were for mean annual temperature (Eq. 10),
354 summer (Eq. 11), and winter (Eq. 12) temperatures (T):

355 (Eq. 10) $\delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (0.50 \times T) - 13.64$

356 (Eq. 11) $\delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (0.46 \times T) - 14.70$

357 (Eq. 12) $\delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (0.52 \times T) - 11.26$

358 (Eq. 10) $\text{MAT} (^{\circ}\text{C}) = 2.38 (\pm 0.10) \times \delta^{18}\text{O}_{\text{mw}} + 28.19 (\pm 0.58)$

359 $\{r^2 = 0.65; n = 304; p \text{ value} < 0.0001\}$

360 Nonetheless, oscillations between glacial and interglacial conditions in the past have influenced global ice
361 volume and sea level fluctuations (Dansgaard, 1964; Shackleton, 1987), impacting seawater oxygen isotope
362 composition and the surface hydrological cycle on a global/worldwide scale, including $\delta^{18}\text{O}_{\text{mw}}$ (Schrag et al.,
363 2002). Prior studies have used sea level information to correct $\delta^{18}\text{O}_{\text{mw}}$ (e.g., Fernández-García et al., 2019;
364 Schrag et al., 2002). Given the chronological uncertainty in the studied levels, a general correction was
365 applied to $\delta^{18}\text{O}_{\text{mw}}$ before temperatures estimations, following Fernández-García et al. (2020) approach.
366 Considering the mean sea level descent for the MIS3 period (50 meters below present-day sea
367 level)(Chappell and Shackleton, 1986), this may have contributed to a potential increase in the global $\delta^{18}\text{O}_{\text{mw}}$
368 value by $\approx 0.56\text{‰}$, inferring a bias in calculated air temperatures of $\approx 1^{\circ}\text{C}$.

369 Following (Pederzani et al., (2021b), mean annual temperatures (MAT) were deduced from the $\delta^{18}\text{O}$ mean
370 average of $\delta^{18}\text{O}_{\text{enrich}}$ values between summer and winter detected in original sinusoidal intratooth profiles
371 (Appendix C) in each tooth before modeling to reduce associated error and maximise number of usable data
372 records. This work shows that comparable results can be obtained before and after model application, but
373 doing it beforehand avoids the associated errors induced by the inverse model. Summer and winter

374 estimations were extracted from the obtained $\delta^{18}\text{O}$ values after inverse modeling application, to identify
375 seasonal variation. o maximize data, in non sinusoidal teeth profiles, MAT was deduced from the average
376 of all points within a tooth. However, this approach is less reliable when complete annual cycles are not
377 recorded. When possible, summer and winter estimations were derived from the obtained $\delta^{18}\text{O}_{\text{carb}}$ values
378 after inverse modelling application, aiming to identify the seasonal amplitude, which is dampened in the
379 original $\delta^{18}\text{O}_{\text{carb}}$ signal.

380 Due to the uncertainties incurred from converting stable isotope measurements to palaeotemperature, the
381 final estimations in this work should be considered exploratory and as a method of standardisation to make
382 results comparable with among different sites, data from different species, and other non-isotopic
383 palaeoclimatic records. In these estimations, the associated error from converting $\delta^{18}\text{O}_{\text{phos}}$ to MAT is
384 enlarged by the uncertainty derived from the transformation of $\delta^{18}\text{O}_{\text{carb}}$ (VPDB) to $\delta^{18}\text{O}_{\text{phos}}$ (VSMOW) (see
385 Pryor et al., 2014; Skrzypek et al., 2016 for further discussion). However, Pryor et al. (2014) and Pederzani
386 et al. (2023) concluded that the impact of this conversion is negligible compared to the error propagation in
387 subsequent calibrations used for temperature estimations from $\delta^{18}\text{O}_{\text{phos}}$. These associated errors were
388 quantified following the methodology outlined by Pryor et al. (2014).

389 **3.5 Inverse modelling applied to intratooth profiles**

390 Intratooth profiles frequently provide a time-averaged signal compared to the input isotopic signal ($\delta^{13}\text{C}/$
391 $\delta^{18}\text{O}_{\text{carb}}$) during enamel formation (Passey et al., 2005b). This signal attenuation is caused by time-averaging
392 effects incurred through the extended nature of amelogenesis and tooth formation, and through the sampling
393 strategy. During mineralisation, the maturation zone, which is time-averaged, often affects a large portion of
394 the crown height and might affect the temporal resolution of the input signal of the sample taken. To obtain
395 climatically informative seasonal information on the analysed teeth, the ~~the~~ inverse modelling method
396 proposed by (Passey et al. (2005b) is applied in this work. This method computationally estimates the time-
397 averaging effects of sampling and tooth formation to obtain the original amplitude of the isotopic input signal
398 more accurately, thus, to summer and winter extremes (Appendix D). This method considers parameters
399 based on the amelogenesis trends of each species and sampling geometry, which are critical for a
400 meaningful interpretation of intratooth isotope profiles. The model also estimates the error derived from the
401 sampling uncertainty and the mass spectrometer measurements to evaluate the data's reproducibility and
402 precision. This method was initially developed for continuously growing teeth, taking into account a constant
403 growth rate within a linear maturation model, with a progressive time-average increment as sampling
404 advances along the teeth profile. The species studied in this research exhibit non-linear tooth enamel
405 formation, particularly in later-forming molars (Bendrey et al., 2015; Zazzo et al., 2012; Passey and Cerling,
406 2002; Kohn, 2004; Blumenthal et al., 2014). Although the model mentioned above is not ideal, as it does not
407 take into account ~~fer~~ non-linear enamel formation and ~~certain~~ specific growth parameters for the species
408 included are unknown, it is the best estimation based on the current state of the field and remains widely
409 used (Pederzani et al., 2023, 2021a, b). Flat and less sinusoidal profiles are less suitable for the application
410 of the model, given its inherent assumption of an approximately sinusoidal form. Therefore, we chose not to
411 apply this methodology in the analysis of intratooth $\delta^{13}\text{C}$ profiles, and it is recommended to approach the
412 interpretation of model outcomes for non-sinusoidal $\delta^{18}\text{O}$ curves with caution. Further details on the
413 application of this method can be found in Appendix D.

414 Following Pederzani et al. (2021b), mean annual temperatures (MAT) were deduced from the average of
415 $\delta^{18}\text{O}_{\text{carb}}$ values between summer and winter detected in original sinusoidal intratooth profiles (Appendix C).
416 This work shows that comparable results for annual means can be obtained before and after model
417 application, but doing it beforehand avoids the associated errors induced by the inverse model. To maximize
418 data, in non-sinusoidal teeth profiles, MAT was deduced from the average of all points within a tooth.
419 However, this approach is less reliable when complete annual cycles are not recorded. When possible,

420 summer and winter temperature estimations were derived from the obtained $\delta^{18}\text{O}_{\text{carb}}$ values after inverse
421 modelling application, aiming to identify the corrected seasonal amplitude, which is dampened in the original
422 $\delta^{18}\text{O}_{\text{carb}}$ signal.

423

424 **3.64 Present-day isotopic and climatic data**

425 Present-day climatic conditions surrounding each site have been considered, allowing an inter-site
426 comparison, essential for compare our this study but also a regional to a with other regional and global
427 perspective data. Considering current MATs and MAPs, estimated climatic data is expressed in relative
428 terms as MAT and MAP anomalies. Present-day summer and winter temperatures were also considered.
429 Present-day temperatures and precipitation values were obtained from the WorldClim Dataset v2 (Fick and
430 Hijmans, 2017) (Appendix B). This dataset includes the average of bioclimatic variables between 1970-2000
431 in a set of raster files with a spatial resolution every 2.5 minutes. The exact location of the selected archo-
432 palaeontological sites was used, using geographical coordinates in the projection on modern climatic maps
433 with QGIS software.

434 Present-day $\delta^{18}\text{O}_{\text{mw}}$ values from the analysed sites' areas were obtained using the Online Isotopes in
435 Precipitation Calculator (OIPC Version 3.1 (4/2017); Bowen, 2022) based on datasets collected by the
436 Global Network for Isotopes in Precipitation from the IAEA/WMO (Appendix B).

Table 2. Mean, maximum value (Max), minimum value (Min), and standard deviation (SD) of $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ values per archaeological site and level organised by cultural periods. **CCE,** calcium carbonate equivalent; **n=** number of intratooth subsamples measured. In tooth type: position (U, upper; L, lower); laterality (R, right; L, left); tooth (M, molar; P, premolar).

4. Results

In northwestern Iberia, specifically in the Vasco-Cantabrian region, the mean $\delta^{13}\text{C}_{\text{carb}}$ values range from -13.8‰ to -8.94‰, with a mean value of -11‰ (SD = 1.2‰) (Table 2; Table 3). Considering species' different fractionation-enrichment factors, the $\delta^{13}\text{C}_{\text{carb}}$ were transformed in $\delta^{13}\text{C}_{\text{diet}}$, resulting in mean values that extend from -27.23‰ to -23.52‰ (Fig. 4). It must be considered that average values may reflect slightly different periods or be affected by seasonal bias because different teeth encompass different diverse periods, but it has been verified in our teeth that the variations are limited when the seasonal information of the sequential sampling is incorporated (± 0.2 ; Appendix B). The carbon isotopic composition varies between species. The bovines have generally higher mean $\delta^{13}\text{C}_{\text{carb}}$ (from -12.48‰ to -8.94‰) than the horses (from -12.6‰ to -11.34‰), whereas the red deer samples fall within the horses' range (from -14.3‰ to -11.3‰). Average values of $\delta^{18}\text{O}_{\text{carb}}$ in all Vasco-Cantabrian individuals extend between -7.23‰ and -3.37‰ (mean = -5.5‰; SD = 0.8‰). When transformed to $\delta^{18}\text{O}$ expected from meteoric waters ($\delta^{18}\text{O}_{\text{mw}}$), with species-adapted correlations, the $\delta^{18}\text{O}_{\text{mw}}$ values range from -10.63‰ to -5.59‰. Less clear patterns in $\delta^{18}\text{O}_{\text{carb}}$ are observed between bovines and horses, with mean values of -5.7‰ and -5.2‰, respectively. In the Mediterranean area, the site of Canyars, both species have relatively high $\delta^{18}\text{O}_{\text{carb}}$ values that fall inside the range of variation observed in the Cantabria region, between -5.53‰ and -3.65‰ in bovines and between -4.84‰ and -4.48‰ in case of horses.

Table 3. Mean $\delta^{13}\text{C}$ from enamel carbonate ($\delta^{13}\text{C}_{\text{carb}}$) and diet ($\delta^{13}\text{C}_{\text{diet}}$), and $\delta^{18}\text{O}$ from enamel carbonate ($\delta^{18}\text{O}_{\text{carb}}$) and meteoric waters ($\delta^{18}\text{O}_{\text{mw}}$), by species on the Vasco-Cantabrian and Mediterranean-northeastern Iberia areas. Max: maximum value; Min: minimum value; SD: standard deviation.

4.1 Axlor (ca. 80 ka BP - 5045 ka cal BP)

A total of seven bovine teeth were included from levels III (n = 4), IV (n = 1), and VI (n = 2) of Axlor cave (Pederzani et al., 2023). The mean $\delta^{13}\text{C}_{\text{carb}}$ range from -9.9‰ to -8.9‰ ($\delta^{13}\text{C}_{\text{diet}} = -24.3\text{‰}$ to -24.5‰); whereas mean $\delta^{18}\text{O}_{\text{carb}}$ values are between -6.2‰ and -4.8‰ ($\delta^{18}\text{O}_{\text{mw}} = -8.3\text{‰}$ and -6.5‰), indicating a range of variation around 1‰ and 1.4‰, respectively (Fig. 3; 4). Considering isotopic compositions by levels, mean $\delta^{13}\text{C}_{\text{carb}}$ decreases from level III to level IV, whereas mean $\delta^{18}\text{O}_{\text{carb}}$ remains stable through the sequence (Table 2; Appendix B). A range between 0.3‰ and 0.5‰ is observed in $\delta^{13}\text{C}_{\text{carb}}$ variation within tooth profiles. Individuals show clear $\delta^{18}\text{O}$ sinusoidal profiles, with peaks and troughs, and intratooth ranges from 2.1‰ to 3.4‰. The $\delta^{18}\text{O}_{\text{mw}}$ after inverse modelling intratooth profiles range from -9.1‰ to -7.3‰ (Appendix C; D). Mean Annual Temperatures (MATs), estimated from mean $\delta^{18}\text{O}_{\text{mw}}$ values, with seasonal control, oscillated between 10.9°C and 12.6°C (MATAs = $-3.1/+0.4/+1.8/-2.1\text{°C}$) (Table 4). From sinusoidal profiles, summer temperatures were extracted from peaks, which are estimated to extend resulting from 15.4°C to 23.7°C , and winter temperatures from troughs provided values ranging from -7°C to 10.8°C . Mean Annual Precipitation (MAPs), extracted from $\delta^{13}\text{C}_{\text{carb}}$, extend between 204mm and 326mm (MAPAs = $-843\text{mm}/-721\text{mm}$). Based on these estimations, a non-clear climatic trend is observed through these levels.

4.2 El Castillo (ca. 75 ka BP - 42.97 ka cal BP)

482 From El Castillo, this work includes bovines (n = 11), horses (n = 5), and red deer (n = 1) teeth from the
483 Mousterian (21 and 20E) and the Transitional Aurignacian levels (18B and 18C). The mean $\delta^{13}\text{C}_{\text{carb}}$ values
484 are lower for horses, bovines, and red deer (-13‰ to -10.2‰) than other sites. Between -12.4‰ and -10.2‰
485 for bovines ($\delta^{13}\text{C}_{\text{diet}} = -24.6‰$ to $-25.8‰$) and between -12.6‰ and -11.5‰ for horses ($\delta^{13}\text{C}_{\text{diet}} = -26.3‰$ to
486 $-25.2‰$) (Fig. 3). The mean $\delta^{18}\text{O}_{\text{carb}}$ values extend from -6.8‰ and -3.3‰. Horses and bovines overlap in
487 their isotopic niche (Fig. 4), mainly due to the notably lower $\delta^{13}\text{C}_{\text{carb}}$ reported by bovines. The mean $\delta^{13}\text{C}_{\text{carb}}$
488 (-13‰) of the single red deer tooth is inside the variation range of bovines and horses but with a lower
489 $\delta^{18}\text{O}_{\text{carb}}$ mean value (-6.8‰). Considering these isotopic compositions by levels, bovine mean $\delta^{13}\text{C}_{\text{diet}}$ values
490 highly increase the variation range from Mousterian levels (20E and 21A) to Transitional Aurignacian levels
491 (18C and 18B). In contrast, horses increase mean $\delta^{13}\text{C}_{\text{diet}}$ values (Fig. 5). Bovine mean $\delta^{18}\text{O}_{\text{mw}}$ values
492 decrease from level 21A to level 18B, while horses from 18B have a large intra-level amplitude.

493 The mean $\delta^{18}\text{O}_{\text{carb}}$ values from horses have a more significant variation (range = 3.3‰) than bovines (range
494 = 2.2‰). All individuals show flat $\delta^{13}\text{C}_{\text{carb}}$ intratooth profiles (<0.4‰), except for red deer (1‰) (Appendix C).
495 Intratooth $\delta^{18}\text{O}_{\text{carb}}$ ranges of individuals are around 1-2‰ for horses and 1-3‰ for bovines. Some of the
496 individuals analyzed do not show non-complete annual cycles. No precise $\delta^{18}\text{O}_{\text{carb}}$ sinusoidal profiles are
497 detected in three teeth; the other six have particularly unclear profiles. After modelling, individual $\delta^{18}\text{O}_{\text{carb}}$
498 ranges oscillated between 2.7‰ and 7.4‰ (Appendix D). MATs oscillated between 4.6°C and 12.6°C
499 (MATAs = -8.8°C/-0.9°C), with mean summer temperatures from around 20.5°C and mean winter
500 temperatures around -1.1°C. MAPs extend between 376mm and 784mm (MAPAs = -656/-248mm) (Table
501 4). Non-important differences in rainfall estimations based on bovines and equids are noticed, probably
502 because they feed on similar ecological resources. Diachronic trends are unclear along the sequence, but
503 mean annual and winter temperatures from levels 18C and 18C seem slightly lower. MAPs estimations
504 oscillated more in the upper levels.

512 **4.3 Labeko Koba (ca. 43.4-35.4 ka cal BP)**

Formatted: Subscript

513 This work includes teeth of bovines (n = 4), horses (n = 4), and red deer (n = 1) teeth from levels related to
 514 Châtelperronian (IXb inf), ProtoAurignacian (VII), and Aurignacian (VI, V, and IV). Significant differentiation
 515 in mean $\delta^{13}\text{C}_{\text{carb}}$ between bovines and horses is observed, with higher values between -9.3‰ and -10.4‰

516 in bovines ($\delta^{13}\text{C}_{\text{diet}} = -25.23.8\text{‰}$ to $-23.8-25\text{‰}$) than equids, whose values extend from -1244.6‰ to $-$
517 4211.6‰ ($\delta^{13}\text{C}_{\text{diet}} = -25.82\text{‰}$ to -25.28‰) (Fig. 3). These horses' values are within the ranges observed
518 from this species in the region. Red deer have similar $\delta^{13}\text{C}_{\text{carb}}$ values to those of horses ($\delta^{13}\text{C}_{\text{carb}} = -12.3\text{‰}$;
519 $\delta^{13}\text{C}_{\text{diet}} = -25.5\text{‰}$). Mean $\delta^{18}\text{O}_{\text{carb}}$ values are similar between species from $-7.24.7\text{‰}$ to $-4.77.2\text{‰}$ ($\delta^{18}\text{O}_{\text{mw}} =$
520 $-8.56.4\text{‰}$ to $-6.18.5\text{‰}$). However, bovines have a very high variation within mean $\delta^{18}\text{O}_{\text{carb}}$ values (2.1‰),
521 also reflected in the intratooth profiles. These $\delta^{18}\text{O}$ values are lower than in other Vasco-Cantabrian sites,
522 especially for two individuals in levels VII and V (Table 3). Differences in $\delta^{13}\text{C}_{\text{diet}}$ values between bovines
523 and horses result in isotopic niche differentiation between both species (Fig. 4). The red deer niche is placed
524 within the horses' niche. The evolution of ~~red this deer~~ niche over time cannot be evaluated by levels due to
525 the limited sample. Considering the isotopic compositions by levels (Fig. 5), both bovines and horses
526 experienced a slight increase in mean $\delta^{13}\text{C}_{\text{diet}}$ from levels IX inf to IV, ~~that is~~, from Châtelperronian to
527 Aurignacian. Mean $\delta^{18}\text{O}_{\text{mw}}$ values of bovines decrease from VII to V, whereas ~~in the case of horses increase~~
528 ~~from XIinf to VI to the~~ horses increase from XIinf to VI to decrease from VI to IV.

Formatted: Subscript

Formatted: Subscript

529 Variability of $\delta^{13}\text{C}_{\text{carb}}$ values in intratooth profiles is slightly higher (0.1-0.7‰), especially in bovines (0.3-
530 0.9‰), with more oscillating profiles than generally flat profiles observed in horses and red deer (Appendix
531 C; D). Intratooth profiles ranges of $\delta^{18}\text{O}_{\text{carb}}$ are also larger within bovines (2-4‰) than in horses (1-2‰).
532 Inverse-modelled individual $\delta^{18}\text{O}_{\text{carb}}$ ranges oscillated between 5-8‰ and 2-4‰, respectively. Sinusoidal
533 curves are observed ~~both~~ in horses and bovines, but bovine profiles are noisier. The red deer has a large
534 extensive $\delta^{18}\text{O}_{\text{carb}}$ range (6.3‰) from summer peak to an incomplete winter thought. We detect an inverse
535 relation between $\delta^{13}\text{C}_{\text{carb}}$ and $\delta^{18}\text{O}_{\text{carb}}$ in some points of these individual profiles. MATs oscillated between
536 5.27°C and $11.43.7\text{°C}$ (MATAs = $-5.6/+1.1\text{°C}$), with summer temperatures from $14.5.3\text{°C}$ to 27.35°C and
537 winter temperatures from $0.1.9\text{°C}$ to $-4.99.4\text{°C}$. MAPs extend between 248mm and 521mm, which are
538 notable drier conditions notably drier than nowadays (MAPAs = -798/-525mm) (Table 4). Lower rainfall levels
539 and higher seasonal amplitudes are recorded along the sequence, especially in samples from the
540 ProtoAurignacian level VII. Relevant differences are noticed between MAPs estimated from bovines and
541 equids, the first providing more arid conditions.

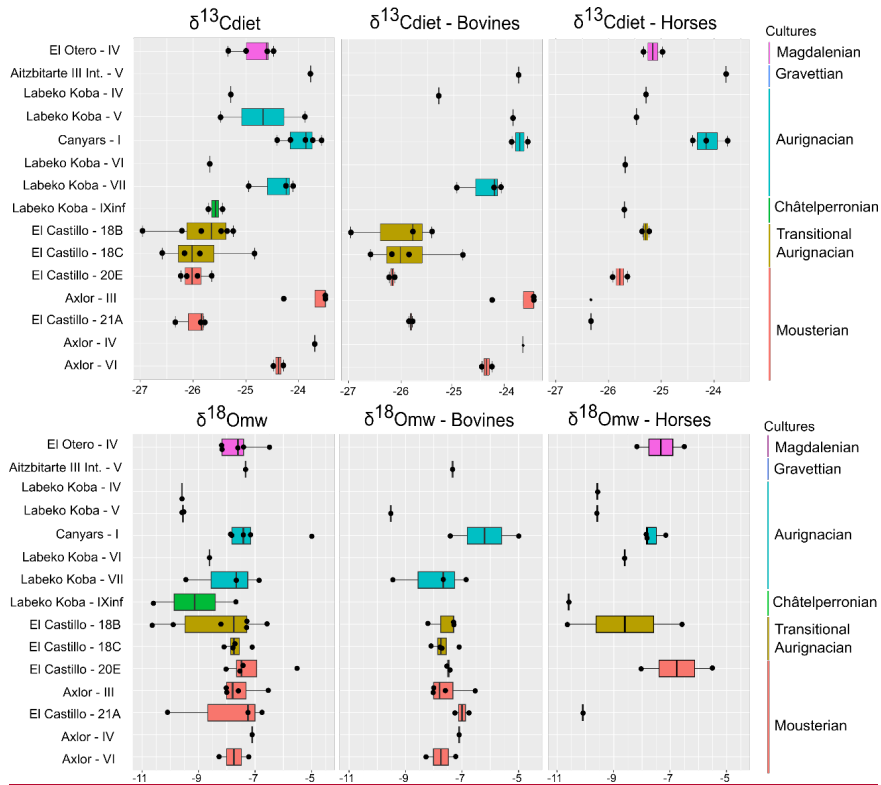

542 4.4 Aitzbitarte III interior (ca. 30.8-26.9 ka cal BP)

543 A single bovine individual was analysed from Gravettian level V located in the inner part of the cave-related
544 to Gravettian. It has a high mean $\delta^{13}\text{C}_{\text{carb}}$ (-9.2‰) considering the observed range in bovines from the Vasco-
545 Cantabrian region, whereas the $\delta^{18}\text{O}_{\text{carb}}$ mean value (-5.5‰) is inside the common $\delta^{18}\text{O}_{\text{carb}}$ variation
546 observed (Fig. 3). The mean $\delta^{13}\text{C}_{\text{diet}}$ value of -23.8‰ is comparable with Canyars and some individuals from
547 Axlor, but different from Labeko Koba and El Castillo individuals. The individual $\delta^{13}\text{C}_{\text{carb}}$ fluctuation is small
548 slight (0.3‰) (Appendix C; D). These teeth show not quite sinusoidal profile shape in $\delta^{18}\text{O}_{\text{carb}}$, with an
549 intratooth range of around 2.2‰. Climatic information is extracted but may be considered cautiously due to
550 the profile shape and the limited sample size. From the inverse modelled mean $\delta^{18}\text{O}_{\text{mw}}$ value (-5.4‰), we
551 estimate a MAT of 134.5°C (MATA = $-0.4/+1.1\text{°C}$) with a summer temperature of $19.7.5\text{°C}$ and winter
552 temperature of -2.94°C . The MAP estimation reached 235mm (-1127mm to nowadays) (Table 4).

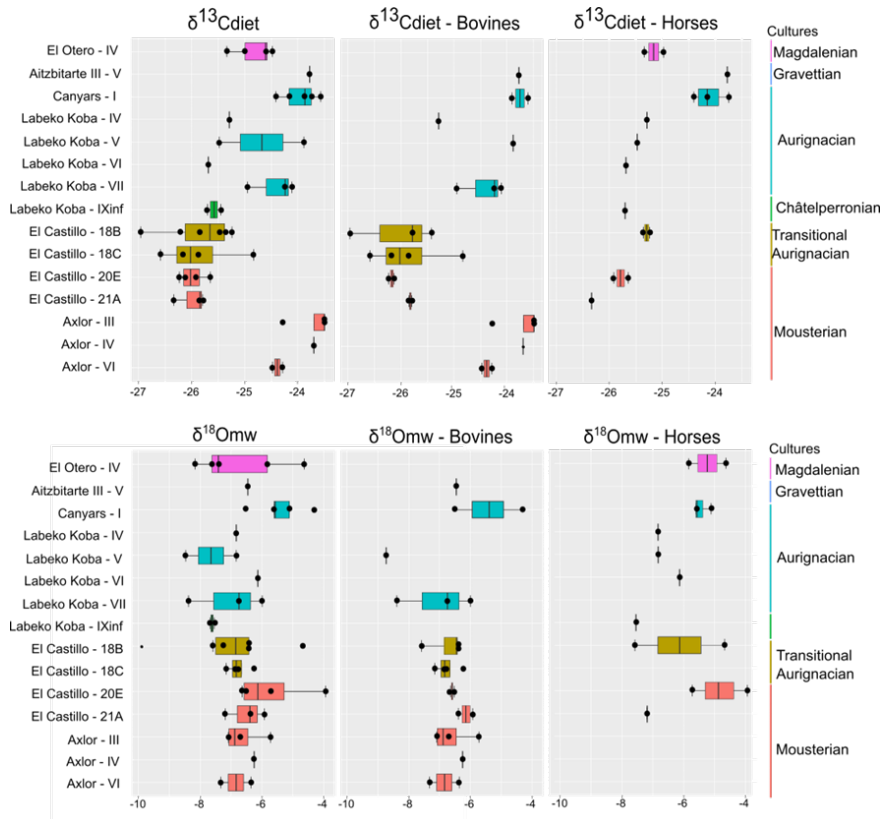

553 4.5 El Otero (ca. 19 ka cal BP)

554 Two equids and three cervids are included from level IV from El Otero, recently redated and chronologically
555 related to the Magdalenian phase (Marín-Arroyo et al., 2018). The mean $\delta^{13}\text{C}_{\text{carb}}$ values are close, between
556 -11.43‰ and -11.34‰ for red deer ($\delta^{13}\text{C}_{\text{diet}} = -24.4\text{‰}$ and -24.6‰) and -11.63‰ and -11.36‰ for horse
557 ($\delta^{13}\text{C}_{\text{diet}} = -25.3\text{‰}$ and -25.3‰) (Fig. 3). These $\delta^{13}\text{C}$ values for both species are relatively high concerning
558 other studied samples, especially for cervids (around +1-2‰). Both species have higher $\delta^{18}\text{O}_{\text{carb}}$ values
559 concerning the common range of variation observed in the Vasco-Cantabria region, between -53.9‰ and $-$
560 3.95‰ for horses and between $-5.14.4\text{‰}$ and $-4.45.4\text{‰}$ for red deer. When values are transformed to $\delta^{13}\text{C}_{\text{diet}}$
561 and $\delta^{18}\text{O}_{\text{mw}}$, equids and cervids isotopic niches are separated (Fig. 4). All individuals show low-amplitude

562 $\delta^{13}\text{C}_{\text{carb}}$ intratooth profiles (<0.3‰), but especially equids with an intratooth variation around 0.1‰ (Appendix
563 C; D). Equids and cervids show $\delta^{18}\text{O}_{\text{carb}}$ sinusoidal profiles, with intratooth ranges between 1.4‰ and 2.4‰.
564 Climatic estimations are proposed only for equids, providing MATs estimations from 13.48.8°C to 12.6.7°C
565 (MATAs = -4.90.3°C/-1.3°C) and MAP between 400mm and 456mm (MAPAs = -755/-699mm) (Table 4). A
566 high-temperature seasonality can be seen, with summer temperatures between 19.7.4°C and 23.82.5°C and
567 winter temperatures from 0.7.10.4°C to -3.17.2°C.

568

569

570 **Figure 5.** Evolution of $\delta^{13}\text{C}$ in diet ($\delta^{13}\text{C}_{\text{diet}}$) and $\delta^{18}\text{O}$ in meteoric waters ($\delta^{18}\text{O}_{\text{mw}}$) by archaeological levels in a diachronic order.
 571 From right to left: all species, including cervids, bovines and horses. Colors correspond to different chrono-cultures.

572 **4.6 Canyars (ca. 40 ka cal BP)**

573 From the archaeological [layer-level I](#) at Canyars, corresponding to the Aurignacian, this work includes
 574 bovines ($n = 2$) and equids ($n = 3$) teeth. The mean $\delta^{13}\text{C}_{\text{carb}}$ values for bovines are between -9‰ to -9.3‰
 575 ($\delta^{13}\text{C}_{\text{diet}} = -23.6\text{‰}$ and -23.8‰), and for horses between -10‰ and -10.7‰ ($\delta^{13}\text{C}_{\text{diet}} = -23.7\text{‰}$ and -24.4‰)
 576 (Fig.3). In this site, the $\delta^{13}\text{C}_{\text{carb}}$ values for horses are notably higher than [samples](#) in the Vasco-Cantabrian
 577 region (around $+1\text{‰}$) (Table 3). Both species have relatively high $\delta^{18}\text{O}_{\text{carb}}$ values, but they fall inside the
 578 range of variation observed in the Vasco-Cantabrian region, between -5.5‰ to -3.6‰ in bovines
 579 and between -4.84‰ and -4.48‰ in horses. **Different responses are seen in mean $\delta^{18}\text{O}$ values between the**
 580 **two bovines, with one high mean value, but with close $\delta^{13}\text{C}$ mean values.** Bovine and equid isotopic
 581 niches overlap (Fig. 4), **but different responses are seen in mean $\delta^{18}\text{O}_{\text{mw}}$ values between the two bovines,**
 582 **with one high mean value but close $\delta^{13}\text{C}_{\text{diet}}$ mean values.**

583 All individuals show flat $\delta^{13}\text{C}_{\text{carb}}$ intratooth profiles ($<0.3\text{‰}$ variation). Some individuals analysed do not show
 584 $\delta^{18}\text{O}_{\text{carb}}$ sinusoidal profiles, with intratooth profiles moderately flat and ranging from 1.14‰ to 1.66‰ . We
 585 detect an inverse relation between $\delta^{13}\text{C}_{\text{carb}}$ and $\delta^{18}\text{O}_{\text{carb}}$ in some points of bovine individual isotopic profiles.
 586 MATs oscillated between 42.59°C and 114.98°C (MATAs = -5.42‰ to -3.32‰), with summer
 587 temperatures from 16.35°C to 27.52°C and winter temperatures from 7.30°C to 1.84°C (Table 4).

Formatted: Subscript

588 MAPs extend between 211mm and 316mm (MAPAs = -431/-326mm). No substantial differences are noticed
 589 in the estimations based on bovines and equids because mean $\delta^{13}\text{C}$ diet values differed relatively little.

592 **Table 4.** Summary of paleoclimatic estimations, based on $\delta^{18}\text{O}$ for temperatures (Mean Annual Temperatures, MAT; summer;
593 winter) and in $\delta^{13}\text{C}$ for precipitation (Mean Annual Precipitations, MAP). Only teeth with validated seasonal curves are included
594 in the summer and winter temperature estimations were obtained from teeth with clear seasonal profiles after modelling, teeth
595 peaks and trough while MAT was averaged between summer and winter before modelling profiles. For in cases some of profiles
596 with an unclear seasonal shapes, MATs were deduced from the original average of all points of the teeth profiles with an
597 unclear seasonal shape, MAT was deduced from the original average of all teeth points without a seasonal profile (values marked
598 in red italics). Mean Details on teeth selection are presented in Appendix B. error associated to temperature estimations is 5.1 ± 0.6
599 (see details in Appendix B). Seasonality is calculated as the temperature difference between summer and winter.

600 5. Discussion

601 5.1 Diet and ecological niches: carbon ratios

602 Carbon isotopic ratios are valuable indicators for discerning past animal diets based on the ecosystems or
603 parts of the ecosystem where the animals most frequently foraged. They are also, partially influenced by
604 the physiology of the animal. Considering species trends in the studied sites, bovines have generally higher
605 mean $\delta^{13}\text{C}_{\text{carb}}$ values (from ~~-12.4‰~~ ~~-8.9‰~~ to ~~-12.4‰~~ ~~-8.9‰~~) than horses (from ~~-12.6‰~~ ~~-11.3‰~~ to ~~-11.3‰~~ ~~-12.6‰~~),
606 whereas the red deer fall within the horses' range (from ~~-13‰~~ ~~-11.3‰~~ to ~~-11.3‰~~ ~~-13‰~~). In Canyars,
607 in the Mediterranean site of Canyars area, bovines also show higher mean $\delta^{13}\text{C}_{\text{carb}}$ values (-9‰ to -9.3‰)
608 compared to horses (-10.7‰ to -10.7‰). These differentiated isotopic ranges for equids and bovines can
609 be potentially linked to feeding behaviour, but, Still, these species are expected to present different basal
610 $\delta^{13}\text{C}_{\text{carb}}$ driven not only by their feeding behavior but also by their by their feeding behaviour and distinct
611 physiological characteristics considering their physiology and diet. Bovines, being ruminants, have been
612 suggested in previous studies to exhibit higher $\delta^{13}\text{C}_{\text{carb}}$ values due to increased methane production (Cerling

613 and Harris, 1999; Tejada-Lara et al., 2018). Therefore, transforming $\delta^{13}\text{C}_{\text{carb}}$ to $\delta^{13}\text{C}_{\text{diet}}$ values [using species-](#)
614 [specific equations](#) is crucial to mitigate the species-specific impact, particularly when comparing ruminants
615 and non-ruminants. Bovines report $\delta^{13}\text{C}_{\text{diet}}$ values between ~~-27.5‰~~ ~~-23.5‰~~ and ~~-23.5‰~~ ~~-27.5‰~~ and horses
616 between ~~-26‰~~ ~~-25‰~~ and ~~-26‰~~ ~~-25‰~~. These carbon compositions are typical of animals feeding on C3
617 plants (commonly accepted range between -34‰ and -23‰), as can be expected from high-latitude
618 ecosystems during the Pleistocene (Cerling and Harris, 1999; Bocherens, 2003; Drucker, 2022).

619 Environmental factors such as light exposure, water stress, temperature fluctuations, salinity, and
620 atmospheric CO_2 changes can influence variations in $\delta^{13}\text{C}$ values in a diet primarily based on C3 plants
621 (Kohn, 2010; Bocherens, 2003). Typically, $\delta^{13}\text{C}_{\text{diet}}$ values below -27‰ ($\delta^{13}\text{C}_{\text{carb}} = -13‰$) are associated with
622 animals feeding on C3 vegetation found in closed forested environments, whereas $\delta^{13}\text{C}_{\text{diet}}$ values between
623 -27‰ and -23‰ are linked to C3 open landscapes, which could include grasslands and steppe areas
624 (Bocherens, 2003). The relatively high $\delta^{13}\text{C}_{\text{diet}}$ observed here points to animals predominantly feeding in
625 open environments. The canopy effect, characterised by a depletion in ^{13}C isotopes due to dense tree cover,
626 seems unlikely among the analysed samples since none of the individuals reported $\delta^{13}\text{C}_{\text{diet}}$ below the
627 [common-standard](#) cut-off of -27‰ (van der Merwe, 1991; Kohn, 2010; Drucker et al., 2008). Therefore, in
628 general terms, open mosaic landscapes, ranging from light forests to meadows and grasslands, can be
629 inferred for northwestern Iberia. Given the generally higher $\delta^{13}\text{C}_{\text{diet}}$ values reported by bovines, it is likely
630 that they were foraging in more open environments than horses and can be considered predominantly
631 grazers. Particularly, bovines from El Castillo exhibit distinct feeding behaviour compared to other Vasco-
632 Cantabrian sites, as evidenced by their lower $\delta^{13}\text{C}_{\text{diet}}$ values, indicating a potential preference for browsing
633 and feeding in closer environments, possibly in lightly forested areas. Both extinct aurochs (*Bos primigenius*)
634 and steppe bison (*Bison priscus*) are usually classified as grass-dominant mix-feeders during the
635 Pleistocene, although it should be noted that modern European bison (*Bison bonasus*) could include
636 browsing in their diet (Rivals et al., 2022). For aurochs, a browse-dominated mixed feeding behaviour is also
637 frequently described.

638 The $\delta^{13}\text{C}_{\text{diet}}$ range in equids [also](#) indicates feeding in open environments ~~as well~~, suggesting a general
639 ~~mixed~~-feeding pattern for the Vasco-Cantabrian region. However, individuals from ~~the the~~ ~~northeastern~~
640 ~~Mediterranean- Iberia area~~ are likely grazing in more open environments, as evidenced by their notably
641 higher $\delta^{13}\text{C}_{\text{diet}}$ values compared to the Vasco-Cantabrian region (+1-2‰). ~~It is important to evaluate if other~~
642 ~~factors are contributing to lower $\delta^{13}\text{C}_{\text{diet}}$ values in horses~~ [Evaluating if other factors contribute to lower \$\delta^{13}\text{C}_{\text{diet}}\$](#)
643 [values in horses is critical](#). In the case of equid ~~samples~~ from the Vasco-Cantabrian region, it should be
644 considered that they have been pretreated with a combination of NaClO and acetic acid, which could
645 potentially affect the isotopic values. Samples after organic removal pretreatment can potentially show either
646 higher or lower $\delta^{13}\text{C}$ values and higher $\delta^{18}\text{O}$ values based on previous experiments (Pellegrini and Snoeck,
647 2016; Snoeck and Pellegrini, 2015), with $\delta^{13}\text{C}$ values generally varying below 0.3‰. Based on the
648 observation that horses in the Vasco-Cantabrian region present lower $\delta^{13}\text{C}_{\text{carb}}$ values compared to bovines
649 but similar mean $\delta^{18}\text{O}_{\text{carb}}$ value ranges, the influence of the pre-treatment on our samples is deemed to be
650 limited.

651 Furthermore, the high variability in $\delta^{18}\text{O}_{\text{carb}}$ values at El Castillo and Labeko Koba does not correlate with a
652 significant variation in $\delta^{13}\text{C}_{\text{carb}}$ values. Based on dental wear and stable isotopes analysis, Middle and Late
653 Pleistocene horses (*Equus ferus*) were primarily grazers, although some rare cases have been reported as
654 mixed feeders or browsers, such as at Igue des Rameaux ~~ament or and~~ Schöningen (Kuitens et al., 2015;
655 Rivals et al., 2009, 2015; Uzunidis, 2020). Horse populations from northern and eastern Europe were found
656 to be browsers or mixed feeders, while those from the Mediterranean region tend to be grazers (Rivals et
657 al., 2022).

Formatted: Superscript

Formatted: Subscript

Formatted: Subscript

658 Finally, the few cervids included in this study exhibit $\delta^{13}\text{C}_{\text{diet}}$ values that frequently overlap with ~~these of~~
659 horses, indicating a mixed feeding behaviour that varies from more closed environments in El Castillo to
660 more open habitats in El Otero. During the Pleistocene, the red deer (*Cervus elaphus*) exhibit a flexible,
661 mixed-feeding ~~behavior~~behaviour, consuming leaves, shrubs, forbs, grass, and sedges, similar to their
662 present-day counterparts (Rivals et al., 2022; Merceron et al., 2021). ~~Today, t~~his species inhabits diverse
663 habitats ranging from steppes to closed temperate forests.

664 5.2 Seasonality, mobility and water acquisition: oxygen ratios and intratooth profiles

665 Average values of $\delta^{18}\text{O}_{\text{carb}}$ in Vasco-Cantabrian individuals extend between ~~-7.2‰ -3.3‰~~ and ~~-3.3‰ -7.2‰~~
666 (Table 3). Even if no clear species patterns in $\delta^{18}\text{O}_{\text{carb}}$ are observed, in general, bovines present slightly
667 lower $\delta^{18}\text{O}_{\text{carb}}$ values from ~~-7.2‰ -4.8‰~~ to ~~4.8‰ -7.2‰~~ than other species; horses have a ~~large-significant~~
668 variation from ~~-6.6‰ -3.3‰~~ to ~~-3.3‰ -6.6‰~~ and red deer from ~~-6.8‰~~ to ~~-4.4‰~~ to ~~-6.8‰~~. In Canyars, both
669 species have relatively high $\delta^{18}\text{O}_{\text{carb}}$ values that fall inside the variation range observed in the Vasco-
670 Cantabrian region, between ~~-5.5‰ and -3.6‰~~ and ~~-5.5‰~~ in bovines and between ~~-4.8‰ -4.4‰~~ and ~~-4.4‰ -~~
671 ~~4.8‰~~ in horses. Each species shows different $\delta^{18}\text{O}_{\text{carb}}$ intratooth ranges, with bovines between 1‰ and 3‰,
672 ~~equids-horses~~ mostly around 1.5‰, and ~~cervids-red deer~~ from 1‰ to 6‰ presenting the higher ranges: ~~from~~
673 ~~1‰ to 6‰~~ (Table 3; Appendix C). After applying inverse modelling to correct the dampening effect (Passey
674 et al., 2005b) (~~Passey et al., 2005~~), the majority of teeth increase the $\delta^{18}\text{O}_{\text{carb}}$ intratooth range, between 3‰
675 and 8‰ for bovines and 2‰ and 7‰ for horses (Appendix D). Most bovines from Axlor and Labeko Koba
676 and ~~equids-horses~~ from El Castillo and El Otero exhibit well-defined sinusoidal profiles in their $\delta^{18}\text{O}_{\text{carb}}$ ~~and~~
677 ~~large~~ intratooth individual ~~ranges~~values, ~~related to the predominant consumption of water sources that~~
678 ~~reflects seasonal indicating potential seasonal~~ fluctuations between $\delta^{18}\text{O}$ values of environmental-summer
679 and winter ~~meteoric waters, A~~ although not all samples ~~consistently~~ follow this pattern ~~consistently, e~~-.
680 ~~Certain~~specific intratooth profiles, particularly those from bovines in El Castillo and Canyars, exhibit sharp
681 profiles with narrow ranges (~~<1.5‰~~). This phenomenon was previously reported in the region in preliminary
682 studies conducted at the sites of El Castillo (Jones et al., 2019) and in the Magdalenian levels of El Mirón
683 cave (Geiling, 2020).

684 Non-sinusoidal profiles observed in the data can be attributed to various factors, including ~~issues related to~~
685 ~~sample techniques and preservation~~sample techniques and preservation issues and the inherent variability
686 in the original isotopic signal. Factors related to sampling and methods can be connected to 1) the sampling
687 process (e.g. too deep or too distant sampling grooves); 2) the imprecision of the mass spectrometer
688 measurements; 3) uncontrolled effects of samples pretreatments; 4) diagenetic alterations affecting the
689 carbonate fraction. However, it must be noted that technical reasons, whether related to sampling or
690 pretreatment, do not appear to impact the obtained results significantly. First, this study reproduces the
691 same intratooth sampling methods that previously yielded reliable results in similar research (e.g., Pederzani
692 et al., 2023, 2021a). Second, non-significant alterations in intratooth profiles of pretreated horse samples
693 (El Castillo, Labeko Koba, Otero) are noticed in comparison to untreated bovid samples (Appendix C). Some
694 bovid samples ~~are equally showing these non-sinusoidal profiles~~show these non-sinusoidal profiles equally.
695 In sites where both species are analysed, no correlation is observed between $\delta^{18}\text{O}_{\text{carb}}$ and $\delta^{13}\text{C}_{\text{carb}}$. In tooth
696 enamel, diagenetic alterations are generally less pronounced than ~~in~~ bone due to its ~~larger-higher~~ mineral
697 content. However, carbonates within tooth enamel can be more susceptible to diagenesis and
698 recrystallisation compared to the phosphate fraction, which contains a ~~larger-more extensive~~ reservoir of
699 oxygen and stronger oxygen bonds (Zazzo et al., 2004; Chenery et al., 2012; Bryant et al., 1996). The
700 carbonate content in our samples, ranging from 3.9% to 8.9%, is similar to the proportion found in modern
701 tooth enamel, suggesting no immediate indication of diagenetic alteration. Diagenesis can also be evaluated
702 by comparing the isotopic values of the carbonate and phosphate fractions in a sample, as there is a
703 predictable difference between them. However, phosphate fraction measurements were still unavailable in

704 our study, ~~except inat the site of Axlor~~ (Pederzani et al., 2023) ~~where good preservation was attested~~.
705 Additionally, in the case of diagenetic alteration, we would expect specimens from the same archaeological
706 levels to be affected similarly, which is not the case.

707 Based on these arguments, it is suggested that the non-sinusoidal $\delta^{18}\text{O}_{\text{carb}}$ signal observed in some
708 individuals ~~may not be attributed to poor preservation; instead, it is~~ likely ~~attributed to the preservation~~
709 ~~reflects~~ the original isotopic signature from water input, ~~which appears to be non-seasonal~~. Several factors
710 can explain why some teeth do not reflect a ~~clear evident~~ seasonal fluctuation, which could be related to
711 animals' mobility ~~or~~, the isotopic composition of the water sources, ~~and seasonal buffering within those water~~
712 ~~sources~~ (Pederzani and Britton, 2019). The main factors considered in our study are 1) the high mobility of
713 the animals analysed among ecosystems with different isotopic baselines due to large migrations; 2) the
714 inland-coastal or short altitudinal movements through the region, which lead to the acquisition of water from
715 sources with different isotopic signal; and 3) the acquisition of water from sources with no clear seasonal
716 signal, such as large bodies of water, rivers, groundwaters, or meltwaters. ~~Furthermore, variability between~~
717 ~~species and within the same species, even within populations living in the same habitat, is also possible.~~
718 ~~This can be attributed to multiple factors, from minor differences in foraging and drinking~~ ~~behaviorbehaviour~~
719 ~~to slight metabolic and physiological variations, including body size, metabolic rate, breathing rate, moisture~~
720 ~~content of food, and faeces, among others~~ (Kohn, 1996; Magozzi et al., 2019; Hoppe et al., 2004).

721 Analyses of nitrogen and sulphur stable isotopes on ungulate bone collagen from Axlor, El Castillo and
722 Labeko Koba (Jones et al., 2019, 2018; Pederzani et al., 2023) have already revealed large variation ranges
723 linked to the existence of several microenvironments just in a few kilometres within the Vasco-Cantabria
724 region. Long migrations and long hunting distances cannot solely explain these ~~diversified-diverse~~ values;
725 ~~because of the range of species involved and their likely small-scale movements~~. In our study, the minimal
726 $\delta^{13}\text{C}_{\text{carb}}$ intratooth variation within individuals (<1‰) indicates limited seasonal changes in their feeding
727 ~~behaviorbehaviour~~ that influenced the carbon isotopic composition (Appendix C). Therefore, considering the
728 ~~diverse topography of the~~ Vasco-Cantabrian, ~~characterized by steep diverse orography with perpendicular~~
729 ~~valleys that connecting~~ the Cantabrian Cordillera with the Atlantic Ocean through rivers over short distances
730 (30-50 km), the availability in the past of a wide range of water sources in small areas seems highly likely.
731 ~~Certain drinking~~ ~~behaviorbehaviours~~ can influence $\delta^{18}\text{O}$, as animals may acquire water from various
732 ~~sources, with small streams better reflecting seasonal isotopic oscillations than large lakes or evaporating~~
733 ~~ponds (see synthesis in~~ Pederzani and Britton, 2019). ~~Systematic consumption of highly buffered water~~
734 ~~sources can significantly attenuate the final recorded signal~~. Furthermore, rivers in the region frequently
735 contain meltwater from snow during the winter-spring months, ~~and water springs are also common~~.

736

737 5.3 Regional trends and ecological niches

738 This study provides valuable insights despite the limited sample size at each archaeological level. It
739 establishes a baseline of isotopic values for northern Iberia, allowing for the evaluation of regional trends.
740 In the northwest, in the Vasco-Cantabrian region, the $\delta^{13}\text{C}_{\text{carb}}$ values obtained oscillated between ~~-13‰ -~~
741 ~~8.9‰~~ and ~~-13‰ -8.9‰~~ and between ~~-7.2‰ -3.3‰~~ and ~~-3.3‰ -7.2‰~~ in the case of $\delta^{18}\text{O}_{\text{carb}}$ values. These
742 values are within the range expected, considering previous regional studies in ungulates (Lécuyer et al.,
743 2021; Pederzani et al., 2023; Jones et al., 2019; Carvalho et al., 2022). Although oxygen variability trends
744 are less precise, the main factor distinguishing the observed changes over time is the variation of carbon
745 isotopic composition among species and regions. The combination of mean $\delta^{13}\text{C}_{\text{diet}}$ and $\delta^{18}\text{O}_{\text{mw}}$ values (Fig.
746 4; 5) accentuates disparities in ecological niche overlap between horses and bovines, whereas cervids and
747 horses frequently exhibit shared ecological niches. The dissimilarities between bovines and horses could

Formatted: Subscript

748 be attributed to shifts in feeding ~~behavior~~behaviour, which may be accompanied by ecological and
749 environmental changes, either independently or in parallel.

750 ~~Upon evaluating the entire dataset by sites~~Comparing the entire dataset and across all sites, the consistently
751 lower $\delta^{13}\text{C}_{\text{diet}}$ values in horses compared to bovids throughout time suggest both animals inhabited open
752 landscapes, with bovines exhibiting a grazer preference while horses show a mix-feeding diet. Only in the
753 Middle-to-Upper Paleolithic transition 18B and 18C levels of El Castillo, an exception is observed with lower
754 $\delta^{13}\text{C}_{\text{diet}}$ values in bovines, linked to a higher browser input due to a higher habitat in closer environments,
755 such as open forests, similar to those inhabited by the horses. This generates a niche overlapping between
756 horses and bovines, most likely reflecting stable conditions that could support both species in similar
757 ecosystems. Contrarily, in the Châtelperronian and early Aurignacian levels from Labeko Koba, a clear
758 differentiation between horses and bovines is observed, mainly in $\delta^{13}\text{C}_{\text{diet}}$ values, highlighting the occupation
759 of different ~~landscapes parts of the landscape~~ by both species. This ~~niche fractionation spatially-driven niche~~
760 ~~separation~~ between species could result from resource competition derived from an unstable climatic period,
761 where species needed to specialise to adapt to the changing conditions. Notable changes are also observed
762 in the $\delta^{18}\text{O}_{\text{carb}}$ values from Labeko Koba compared to the older El Castillo and Axlor sites, with bovines
763 exhibiting a higher fluctuation range and the lowest values in the region. These trends are consistent with
764 values observed on bone collagen from previous studies in the ~~studied~~ sites. During the Middle-to-Upper
765 Paleolithic transition in the region, by comparing horses and red deer, a decrease in mean $\delta^{13}\text{C}$ (from ~~-21.0‰~~
766 to ~~-20.4‰~~) and $\delta^{15}\text{N}$ values (from ~~2.56‰~~ to ~~62.5‰~~) ~~in bone collagen~~ was observed in contrast to stable red
767 deer mean $\delta^{13}\text{C}$ - (Fernández-García et al., 2023; Jones et al., 2018, 2019). This decrease was ~~already~~
768 ~~previously~~ interpreted as niche fractionation, derived from an opening landscape, that drove equids into low-
769 quality pastures compared to cervids. Pollen evidence in the region suggests a prevalence of steppe
770 vegetation and low tree cover for the Châtelperronian and Aurignacian (Iriarte-Chiapusso, 2000).

771 In the same period, ~~Canyars in the northeastern at the Mediterranean site~~area of ~~Canyars~~, higher mean
772 $\delta^{13}\text{C}_{\text{diet}}$ are observed in both species (between $-23.6‰$ and $-24.4‰$), indicating a preference for more open
773 landscapes by bovines and equids. The indication of open areas could be linked to the arid climatic
774 conditions associated with the Heinrich Event 4, which coincides with the formation of the ~~archaeological~~
775 ~~studied level at Canyars~~. This predominance of open areas coincides with the presence of typical steppe
776 herbivore species, such as *Equus hydruntinus* and *Coelodonta antiquitatis*, the microfauna and pollen taxa,
777 and ~~the data offered by the~~ use-wear analysis on ungulate remains identified at the site (Daura et al., 2013;
778 López-García et al., 2022; Rivals et al., 2017).

779 Aridity is a plausible explanation for the higher niche partitioning observed in Labeko Koba and the higher
780 $\delta^{13}\text{C}_{\text{diet}}$ values found in Canyars for both species ~~in during the~~ Aurignacian ~~levels~~. The $\delta^{13}\text{C}_{\text{diet}}$ results of
781 bovines from Aitzbitarte III ~~interior~~ during the Gravettian are consistent with the trend observed in Labeko
782 Koba, ~~and where~~ previous studies have already suggested this time to be notably arid and cold (~~Arrizabalaga~~
783 ~~et al., 2010~~). Finally, in the Magdalenian level of El Otero, higher $\delta^{13}\text{C}_{\text{diet}}$ values resemble those observed in
784 Canyars. However, this time, carbon values are related to niche partitioning between horses and red deer.
785 In contrast, higher $\delta^{18}\text{O}_{\text{mw}}$ values ~~might indicate warmer conditions but are still associated with open~~
786 landscapes in the Vasco-Cantabrian area.

787 5.4 Late Pleistocene climatic evolution in Northern Iberia

788 Carbon and oxygen isotopes were used to estimate quantitative parameters related to past temperatures
789 and precipitation. In the case of oxygen isotopic compositions, an evaluation of environmental water
790 composition can be addressed before approaching temperature estimations. When transformed to $\delta^{18}\text{O}_{\text{mw}}$
791 using species-adapted correlations ~~and correcting bias in sea water~~ $\delta^{18}\text{O}_{\text{mw}}$, the summer $\delta^{18}\text{O}_{\text{mw}}$ values
792 obtained from the modelled teeth range from ~~-84.9-4‰~~ to ~~-42.2-4.9‰~~, while the winter values range from -

Formatted: Subscript

Formatted: Subscript

Formatted: Subscript

Formatted: Subscript

Formatted: Subscript

793 ~~17.0-16.4~~ ~~2‰~~ to ~~-8.94-2~~ ~~-10.6‰~~. These values ~~agree can be tentatively compared~~ with the current ~~trends~~
794 ~~observed in~~ $\delta^{18}\text{O}_{\text{mw}}$ ~~range of values~~ recorded by the IAEA station (IAEA/ WMO, 2022) in Santander (from -
795 3.5‰ in summer to -6.6‰ in winter) and in Barcelona (from -2.2‰ in summer to -6.3‰ in winter) and the
796 OIPC (Bowen, 2022) estimations for studied locations (from -1‰ to -9‰) (Appendix B). As observed in the
797 present, Canyars exhibit ~~higher~~ mean annual $\delta^{18}\text{O}_{\text{mw}}$ values ~~of around -8.25-5‰~~, which ~~are close is lower to~~
798 ~~than~~ the current $\delta^{18}\text{O}_{\text{mw}}$ estimated for this location (-5.4‰) ~~but higher than Labeko Koba mean annual $\delta^{18}\text{O}_{\text{mw}}$~~
799 ~~(-9.5‰)~~. This ~~raises the question of whether suggests that~~ the baseline $\delta^{18}\text{O}_{\text{mw}}$ differences between
800 Canyars and the other sites can be ~~primarily~~ attributed to ~~the~~ Mediterranean influence rather than the
801 Atlantic, assuming equivalent air circulation patterns ~~and moisture sources in the past as~~ experienced ~~in the~~
802 ~~past as~~ in the present (Moreno et al., 2021; Araguas-Araguas and Diaz Teijeiro, 2005; García-Alix et al.,
803 2021) ~~and considering IAEA stations~~.

Formatted: Spanish (Spain)

804 ~~Considering this work's climatic reconstruction, As indicated by the climate reconstructed here,~~ temperatures
805 ~~are were~~ generally colder ~~and precipitation levels were are~~ notably lower ~~in the Late Pleistocene period in~~
806 ~~this region than,~~ and precipitation levels were notably lower ~~in the Late Pleistocene period in this region than~~
807 ~~they are~~ nowadays (Table 4; Appendix B). From 80,000 to ~~57-46 ka-000~~ cal BP, in the Mousterian levels of
808 ~~the Axlor site,~~ temperatures ~~are~~ generally ~~slightly~~ colder than today, ~~but there is no clear trend observed~~
809 ~~throughout the sequence, but with~~ older levels ~~showing showed~~ higher differences between summer and
810 winter temperatures. Rainfall estimations ~~in these levels~~ exhibit an unusual arid pattern, possibly affected
811 by bovines ~~mainly predominantly~~ feeding in open areas ~~at that time,~~ ~~indeed, even if the species' impact has~~
812 ~~been corrected through $\delta^{13}\text{C}_{\text{diet}}$ estimation (Tejada-Lara et al., 2018),~~ ~~this aligns study observed that with~~
813 ~~the impact the influence~~ of basal feeding ~~behavior behaviour~~ on rainfall estimations, ~~as~~ previously advised
814 by Lécuyer et al. (2021) ~~should be considered~~. In this case, it is not possible to isolate the effect of diet from
815 environmental interference, but previous studies have highlighted stable climatic conditions ~~for at~~ the site
816 (Pederzani et al., 2023). ~~Climatic reconstruction, relying on a compilation of lake sediments from northern~~
817 ~~Iberia (Moreno et al., 2012) suggests that from late MIS4 to 60 ka cal BP, cold but relatively humid conditions~~
818 ~~predominated, with drier conditions emerging later. Additionally, stalagmites from the Ejulve cave in the~~
819 ~~Iberian range indicate a dry climate until 65.5 ka BP, preceding HE6, followed by more humid conditions~~
820 ~~afterwards~~ (Pérez-Mejías et al., 2019).

Formatted: Superscript

Formatted: Subscript

821
822 During the ~~late Middle to Upper~~ Paleolithic ~~transition~~ and early Aurignacian occupations, ~~the observed a~~ shift
823 in the niche configuration of species ~~is observed, suggests potential indicating~~ climatic perturbations. There
824 is a decreasing trend in temperatures from the Transitional Aurignacian levels in El Castillo (18C and 18B;
825 ca. 47 ~~ka-000~~ cal BP) to the Châtelperronian (Xinf; 42, ~~1 ka-400~~ cal BP) and Early Aurignacian (VII-V; from
826 41, ~~136.1~~ to 37, ~~88-570 ka~~ cal BP) levels in Labeko Koba. Lower mean annual and winter temperatures are
827 particularly notable ~~at in~~ El Castillo ~~and,~~ while Labeko Koba, ~~Labeko Koba levels~~ exhibits high seasonal
828 amplitude, especially ~~in at~~ level VII. Additionally, there is a slight decrease in rainfall and increased
829 fluctuations from the Transitional Aurignacian levels ~~from in~~ El Castillo (18B-18C) to the Aurignacian levels
830 in Labeko Koba (VII-V). Previous studies in the northern Iberian region underlined an environmental and
831 ecological shift after GS13/HE5, from 48,000 to 44, ~~ka-000~~ cal BP, based on a progressive trend to colder
832 temperatures, aridity increase, and open environmental conditions, matching with the late Neanderthal
833 occupations, followed by a population hiatus before the arrival of Anatomically Modern Humans (Vidal-
834 Cordasco et al., 2022; Fernández-García et al., 2023). This episode coincides with the ~~region's maximum~~
835 ~~extension of the glaciers maximum extent of glaciers in this region, as recorded in Lake Enol and Vega~~
836 ~~Comeya and thean -associated a~~ significant decrease in plant biomass and herbivore abundance ~~around~~
837 ~~44 to 38 ka BP~~ (Jiménez-Sánchez et al., 2013; Ruiz-Fernández et al., 2022; Ballesteros et al., 2020; Vidal-
838 ~~Cordasco et al 2022~~). Moreover, previous isotopic analyses in the region pointed to some ecological

839 alterations considering perturbations observed in the $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ of bone collagen (Jones et al., 2019,
840 2018). This tendency of increased aridity aligns with observations made in regional lake sediments from
841 northern Iberia between 60 and 23.5 ka cal BP, marked by abrupt climate changes associated with HE
842 (Moreno et al., 2012). Supporting this, the marine core MD04-2845 in the northern margin of Iberia reveals
843 a decline in the Atlantic forest and an expansion of steppe and cold grasses from 47 to 40 ka BP (Fourcade
844 et al., 2022).

845 When comparing the environmental reconstruction of the Aurignacian period ~~in-between~~ the Vasco-
846 Cantabrian ~~region~~ (levels V-IV from Labeko Koba) and the ~~Mediterranean northeastern~~ region (Layer I from
847 Canyars), which are synchronous to HE4 (39,000 ka BP), ~~this~~ study reveals notably lower rainfall levels for
848 the ~~northeastern site~~ ~~latter Mediterranean~~. ~~This is, consistent with implied by~~ ~~due to the feeding~~
849 ~~behavior/behaviour described for observed in~~ animals ~~mainly feeding, mainly~~ in open areas. ~~But~~ ~~However,~~
850 ~~These drier conditions align~~ ~~align~~ with the ~~unique-specific~~ climatic ~~expectations-conditions~~ ~~expected~~ for this
851 period and support previous findings ~~suggesting-revealing~~ aridity and the predominance of open landscapes
852 (Rivals et al., 2017; Daura et al., 2013). The temperature data indicates that ~~at-~~ Canyars, ~~colder conditions~~
853 ~~were~~ experienced, ~~colder conditions~~, especially during the winter season, compared to the present.
854 However, in comparison to Labeko Koba, Canyars experienced warmer conditions. As explained earlier, the
855 Mediterranean basin had consistently higher temperatures, even during colder periods. ~~In line with this,~~
856 ~~previous studies conducted at the site have also highlighted the~~ ~~This is consistent with the~~ persistence of
857 Mediterranean open forests in the surroundings, ~~as indicated by other studies~~ (Rivals et al., 2017; López-
858 García et al., 2013). ~~Continuous natural records are lacking in the northeastern Iberian margin. However,~~
859 ~~the inland stalagmite record from Ejulve Cave~~ (Pérez-Mejías et al., 2019) ~~and the sedimentary lacustrine~~
860 ~~sequence of Cañizar de Villarquemado~~ (González-Sampérez et al., 2020) ~~have identified the most arid~~
861 ~~intervals during HE5 and HE4. These periods were characterized by steppe vegetation expansions, followed~~
862 ~~by deciduous woodland expansion. To the south, the Padul sequence agrees with cold and dry conditions~~
863 ~~alternating with forest recovery~~ (Camuera et al., 2019), ~~as documented in the Alborean Sea~~ (Martrat et al.,
864 2004).

865 Finally, the sites Aitzbitarte III ~~interior~~ (26,7,692 ka cal BP) and El Otero (19,303 ka cal BP) provided
866 valuable climatic insights into the Vasco-Cantabrian region during the Upper Paleolithic, specifically during
867 the Gravettian and Magdalenian ~~periods~~, respectively. Considering previous research in the region, the
868 climatic trend reported for the Aurignacian, characterised by colder and more arid conditions, was expected
869 to continue or even intensify during the Gravettian ~~period~~ (Fernández-García et al., 2023; Garcia-
870 Ibaibarriaga et al., 2019b; Lécuyer et al., 2021). Both sites ~~exhibit~~ ~~indicate~~ lower precipitation ~~levels~~
871 ~~compared to the present~~ ~~than~~ ~~presently found in these area~~, indicating significant aridity, supported by
872 ~~the~~ ~~with ungulates animals predominantly feeding in open landscapes predominantly~~ ~~today in this area,~~
873 ~~indicating significant aridity, with ungulates feeding predominantly in open landscapes. Finally, However,~~
874 ~~EEI~~ Otero's higher mean annual temperatures, recorded in the Magdalenian horses ~~respect to other sites~~
875 ~~within the Vasco-Cantabrian~~, are consistent with a climatic amelioration following the Last Glacial Maximum
876 (Jones et al., 2021). MIS 2 is marked by the most extreme glacial conditions, as indicated by NGRIP and
877 marine cores in Iberian margins (Sánchez Goñi et al., 2002; Martrat et al., 2004). However, other regional
878 proxies, such as lake sediment and the stalagmite sequence in Pindal Cave (Moreno et al., 2010), suggest
879 a complex and highly variable climate during MIS 2. These proxies identify the coldest and most arid period
880 within MIS 2 as the interval from 18 to 14 ka cal BP, rather than the global Last Glacial Maximum (23 to 19
881 ka cal BP).

882 5. Conclusions

883 This study provides a ~~comprehensive-detailed~~ analysis of the temporal evolution of the environment and
884 climatic conditions in northern Iberia, spanning from the ~~late~~ Middle Paleolithic to the late Upper Paleolithic,

Formatted: Font: Not Bold

Formatted: Subscript

885 this is from the GS21 to the GS2, ranging from ~~ca. 80 ka BP,000~~ to ~~1975 ka cal,000 cal~~-BP. In the Vasco-
886 Cantabrian region, the results reveal a heterogeneous open mosaic landscape ~~characterised by an open~~
887 ~~mosaic~~, ranging from light forest to meadows and grasslands. This landscape reconstruction is primarily
888 ~~influenced-inferred~~ by the feeding locations of the studied animals and, consequently, related to the
889 ecosystems where hominins captured them. Despite shifts in niche configuration observed between equids
890 and bovines, both species typically foraging in open areas, with bovines showing a higher preference for
891 grazing. Only in El Castillo, during the late Mousterian and the Transitional Aurignacian levels, bovines show
892 unusually low $\delta^{13}\text{C}_{\text{diet}}$ related to higher browsing and overlapping with horse isotopic niche. This might
893 indicate a slightly closed mosaic landscape that could sustain both species. In contrast, only horses from
894 Canyars exhibit a preference for grazing ~~behavior~~behaviour.

895 Stable climatic conditions are described for Mousterian in Axlor and El Castillo levels from ~~80,000~~ to ~~50,000~~
896 ~~ka cal~~ BP. However, some elements indicate ~~some~~ environmental perturbations initiated during the
897 Transitional Aurignacian levels ~~from of~~ El Castillo, around ~~48-46-43 ka ,000~~-BP and after HE5/GS13. After
898 GS12 (~~44,200-43,3 ka00~~ BP), horses and bovines are potentially occupying different ecological niches
899 during the Châtelperronian and early Aurignacian levels ~~from of~~ Labeko Koba, pointing to a species'
900 environmental specialisation, which can be a consequence of competition for food resources during an
901 unstable ecological period. The climatic estimations indicate a temperature shift during this period, with a
902 slight decrease in temperatures and evidence of fluctuations in rainfall ~~from the Transitional Aurignacian~~
903 ~~levels of El Castillo to the early Aurignacian levels of Labeko Koba~~. Previous environmental studies on the
904 region have underlined ecological stress and ~~aridity increase~~increasing aridity from around ~~42.58,000 ka cal~~
905 BP, ~~which could sustain this biological impoverishment~~which may relate to a ~~wibroad~~er ecosystem decline.
906 When comparing the environmental conditions during the Aurignacian period in the Mediterranean northeast
907 (Canyars) and the Vasco-Cantabrian regionnorthwest (Labeko Koba), the Mediterranean are first had
908 higher baseline temperatures but also experienced higher aridity. Animals continued to feed on open
909 landscapes during the Gravettian and Magdalenian levels in the Vasco-Cantabrian region, represented by
910 Aitzbitarte III interior and El Otero sites. However, there is evidence of a temperature recovery after the LGM
911 at the El Otero site.

912 ~~For the first time, a regional approach is obtained by measuring $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ in enamel carbonates from~~
913 ~~ungulates teeth for the late Middle and Upper Paleolithic in northern Iberia. Stable isotope composition of~~
914 ~~oxygen and carbon from ungulate teeth has provided valuable insights into the diet and foraging areas of~~
915 ~~bovines, equids, and cervids. These results, The results presented here, derived from this the first extensive~~
916 ~~sampling in the Vasco-Cantabrian, establish the basis of future stable isotopic studies on teeth faunal tooth~~
917 ~~enamel in this regionIberia, which were slightly explored in the region.~~ Despite the uncertainties inherent in
918 this work, ~~derived from using the carbonate enamel fraction for paleoclimatic estimations,~~ both $\delta^{18}\text{O}$ and
919 $\delta^{13}\text{C}$ contributed to the regional climatic characterisation, including the estimation of temperatures and
920 precipitations, as well as the seasonality range between summer and winter. The potential influence of
921 pretreatment effects and uncontrolled diagenetic alterations on the enamel carbonate fraction has been
922 assessed. However, ~~further investigation~~complementary diagenetical test, using new techniques like
923 ~~$\delta^{18}\text{O}_{\text{phos}}$ phosphate analysis and FTIR analyses are needed~~advised in further works in the region, to gain
924 more insights into sample preservation. Ongoing sulphur, hydrogen and strontium studies will provide
925 additional information on the ~~animal~~-mobility patterns ~~of animals that were hunted by Late Pleistocene~~
926 ~~consumed for~~ hominins and, therefore, ~~will help better understand~~us better understand the landscape
927 ~~exploitation-ecological and environmental context~~ occupied by ~~the~~ through this transition between late
928 Neanderthal and ~~early~~-modern humans ~~groups~~habitations in this region and their landscape use in this
929 ~~particular region~~. Finally, a ~~A~~ more comprehensive characterisation of the baseline oxygen values ~~in the~~
930 ~~region~~would also enhance the environmental interpretation of the existing data.

931 **Appendices**

932 Appendices A, C and D are presented after bibliography. Raw data is ~~found~~-presented in Appendix B. ~~All~~
933 available at https://github.com/ERC-Subsilience/Ungulate_enamel-carbonate

934 **Code availability**

935 R code used to perform plots, [error calculations](#), and models in this manuscript can be accessed at GitHub
936 (https://github.com/ERC-Subsilience/Ungulate_enamel-carbonate).

937 **Data availability**

938 The available datasets used for this article are provided in the supplementary materials (Appendix A-D).

939 **Author contribution**

940 A.B.M.-A. got the funding and designed the research. A.B.M.-A and M.F.-G. get the permissions for sampling
941 in the regional museums. M.F.-G., K.B, and S.P. defined the analysis strategy. M.F.-G. analysed the data
942 and wrote the manuscript with critical inputs from A.B.M.-A., K.B, and S.P. J.M.G., L.A., M.F.-G., and A.C.
943 M.F.-G., L.A., J.M.G., and A.C. achieved the teeth sampling and lab sample preparation. J.D. and M.S. are
944 responsible for the excavations in Canyars and contribute to the discussion. All the authors revised and
945 commented on the manuscript.

946 **Competing interests**

947 The contact author has declared that none of the authors has any competing interests.

948 **Acknowledgements**

Appendix A. Sites description

A1. Vasco-Cantabrian sites

Axlor (Dima, Vizcaya, País Vasco)

Axlor is a rock-shelter located in Dima (43.2706; -1.8905), with a continuous Middle Paleolithic sequence from the MIS5 to the MIS3 (DeMuro et al., 2023; Pederzani et al., 2023; Marín-Arroyo et al., 2018). It is placed on the southwestern slope of the Dima ~~valley~~Valley, with an elevation of approximately 320 m above sea level (a.s.l.), at 33 km straight from the present-day coastline, next to one of the lowest mountain passes linking the Cantabrian basins and the Alavese Plateau. The site was discovered in 1932 and initial excavations were performed by Barandiarán (1967-1974). J. M. Barandiarán undertook the excavations between 1967 and 1974, identifying eight Mousterian levels (I-VIII) (Barandiarán, 1980).

From 2000 to 2008, new excavations by González-Urquijo, Ibáñez-Estévez and Rios-Garaizar were achieved and, since 2019, these are ongoing by González-Urquijo and Lazúen. Due to the lack of chronology during Barandiarán excavations, among other aspects, work was focused on obtaining a detailed stratigraphy on the new excavation areas to correlate it with Barandiarán's levels (González-Urquijo & Ibáñez-Estévez, 2021; González Urquijo et al., 2005). The new stratigraphic sequence is roughly equivalent to the previous one, but with additional levels, not previously identified or excavated by Barandiarán. Some of these levels were deposited before Level VIII (Gómez-Olivencia et al., 2018; 2020). The Middle Paleolithic sequence extends from layers VIII to III (or from N to B-C). Levallois production is predominant in the lower levels (VI to VIII), while Quina Mousterian technocomplex does in the upper ones (from III to V) (Rios-Garaizar, 2012, 2017). ~~New-Recent~~Recent chronological data by radiocarbon (Pederzani et al., 2023; Marín-Arroyo et al., 2018) and OSL (Demuro et al., 2023) methods confirm that a sequence Axlor levels VI, VIII, and VIII probably accumulated during MIS5d-a (109–82 ka), while levels D to B probably were formed during the period encompassing the start of MIS 4 (71–57 ka) through to the beginning or middle of MIS 3 (57–29 ka) (Demuro et al., 2023) and upper Level III to 46,200 ±3,000 BP, which calibrates between 45,540-350 cal BP and ~~the end of beyond~~the calibration curve at > 55,000 cal BP (see Pederzani et al., 2023; Fig. 4).

The archaeozoological study indicates an anthropic origin of the faunal assemblage with scarce carnivore activity documented (Altuna, 1989; Castaños, 2005; Gómez-Olivencia et al., 2018). In lower layers, the most abundant taxa are *Cervus elaphus* (VIII) and *Capra pyrenaica* (VII), while in upper layers III-V, *Cervus elaphus* is substituted by *Bos primigenius*/*Bison priscus* and *Equus sp.* The material included in this work comes from the faunal collection of the Barandiarán excavation currently curated at the Bizkaia Museum of Archaeology (Bilbao), where teeth were sampled, and the stable isotope analyses on enamel phosphate were included in Pederzani et al. (2023).

El Castillo (Puente Viesgo, Cantabria)

El Castillo ~~is~~ is located in Puente Viesgo (43.2924; -3.9656), with an elevation of approximately 195m a.s.l., at 17 km straight from the present-day coastline. The cave belongs to the karstic system that was formed in the Monte Castillo, which dominates the Pas ~~valley~~Valley. The site was discovered in 1903 by H. Alcalde del Río. H. Obermaier carried out the first excavation seasons between 1910 and 1914, when many of the archaeological remains were recovered, mainly from the ~~hall of the cave~~cave hall. These interventions were done under the supervision of the "Institut de Paléontologie Humaine" (IPH) and ~~of~~Prince Albert I of Monaco. From 1980 to 2011, V. Cabrera and F. Bernaldo de Quirós underwent new excavations focusing on the cave entrance, on the Middle to Upper Paleolithic transitional levels, mainly 16, 18 and 20 (Cabrera-Valdes, 1984). The site has yielded an important stratigraphic sequence, composed by 26 sedimentological

1567 units (1-26) related to different anthropic occupational units, often separated by archaeologically sterile units:
1568 Eneolithic (2), Azilian (4), Magdalenian (6 and 8), Solutrean (10), Aurignacian (12, 14, 16 and 18),
1569 Mousterian (20, 21 and 22) and Acheulean (24) (Cabrera-Valdés, 1984).

1570 Unit 21 is mostly sterile (Cabrera Valdés, 1984; Martín-Perea et al., 2023), and ~~it was dated by ESR~~
1571 ~~dated it~~, yielding a mean date of 69,000 ± 9,200 years BP (Rink et al., 1997). However, Martín-Perea et al.
1572 (2023) suggested some dating uncertainty ~~arising from the interpretation of interpreting~~ the initial
1573 stratigraphic nomenclature. They suggest that the ESR dates provided for level 21 by Rink et al. (1997) were
1574 erroneously attributed to this unit and it might correspond to 20E, indicating that below that subunit, the
1575 chronology is older than 70,000 years BP (Martín-Perea et al., 2023). The Mousterian Unit 20 cave is divided
1576 into several subunits (Martín-Perea et al., 2023). In Unit 20, a cave roof collapse took place, transforming
1577 the cave system into an open rock shelter. This unit contains abundant archaeological and paleontological
1578 remains. Lithic industry ~~consistent-consists in-of~~ sidescrapers, denticulates, notches and cleavers, the
1579 majority on quartzite and presents both unifacial, bifacial discoid debitage and Levallois debitage. Unit 20E
1580 was attributed to Quina Mousterian by Sánchez-Fernández and Bernaldo De Quiros (2009) and contains a
1581 Neanderthal tooth ~~remain~~ (Garralda, 2005). Considering the geochronological uncertainties for dates on
1582 20E related ~~with-to~~ Rink et al. (1997), we have decided to ~~solely-rely solely~~ on ESR date of 47,000 ± 9400
1583 BP provided by Liberda et al. (2010) for this level. Unit 20C presents clear evidence of the Mousterian lithic
1584 industry and radiocarbon dates of 48,700±3,400 uncal BP (OxA-22204) and 49,400±3,700 uncal BP (OxA-
1585 22205) (Wood et al., 2018) and mean ESR date of 42,700 ±9900 BP (Liberda et al., 2010). Level 19 is
1586 archaeologically sterile and separates Unit 20 from Unit 18 (Wood et al., 2018).

1587 Unit 18 is divided into ~~three parts~~: 18A (archaeologically sterile), 18B, and 18C. Levels 18B and 18C were
1588 classified as Transitional Aurignacian, representing a gradual transformation from the Mousterian to the
1589 Aurignacian, which is unique to El Castillo cave (Cabrera et al., 2001; Maíllo and Bernaldo de Quirós, 2010;
1590 Wood et al., 2018). The ~~dates and the cultural attribution of these levels~~ ~~levels' dates and cultural~~
1591 ~~attribution~~ have been the subject of much debate (e.g. Zilhao and D'Errico, 2003; Wood et al., 2018).
1592 According to Wood et al. (2018), the last dates of these levels range between 42,000±1,500 uncal BP (OxA-
1593 22203) and 46,000±2,400 uncal BP (OxA-21973), which is much earlier than the start of the Aurignacian
1594 period in the Cantabrian region (Marín-Arroyo et al., 2018; Vidal-Cordasco et al., ~~2023~~2022). The lithic
1595 assemblage of Unit 18 appears to be dominated by Discoid/Levallois technology (Bernaldo de Quirós and
1596 Maíllo-Fernández, 2009) but with a high percentage of "'Upper Paleolithic'" pieces. Additionally, punctual
1597 bone industry, ~~as well as pieces with incisions and engravings, and pieces with incisions and engravings~~
1598 were discovered in Unit 18 (Cabrera-Valdés et al., 2001). Three deciduous tooth crowns attributed to
1599 Neanderthals were found in Unit 18B (Garralda et al., 2022). Above, Unit 17 is sterile but contains scarce
1600 lithic and faunal materials, while Level 16 was attributed to the Proto-Aurignacian, with dates of
1601 38,600±1,000 uncal BP (OxA-22200) (Wood et al., 2018).

1602 According to Luret et al. (2020), there was a shift in hunting practices between the Late Mousterian (unit 20)
1603 and the Transitional Aurignacian (unit 18). During the Late Mousterian, hunting strategies were less
1604 specialized, and the species hunted included red deer, horses, and bovines. However, in Unit 18, a
1605 specialization in red deer hunting is observed. However, the explanation of this shift has been proposed as
1606 a response to a cultural choice or induced by climatic changes. ~~However, recent taphonomic studies by~~
1607 ~~Sanz-Royo et al. (2023) on the old collections of Aurignacian Delta level reveal a more significant role of~~
1608 ~~carnivores than shown by Luret et al. (2020)~~. The material included in this work comes from the faunal
1609 collection recovered during the Cabrera-Valdés and Bernaldo de Quirós excavations curated at Museo de
1610 Prehistoria y Arqueología de Cantabria (MUPAC, Santander).

1611

1612 **Labeko Koba (Arrastre, Guipúzcoa, País Vasco)**

1613 Labeko Koba is a cave ~~located~~ in the Kurtzetxiki Hill (43.0619; -2.4833), at 246 m a.s.l. and 29 km straight
1614 from the present-day Atlantic coast. In 1987 and 1988, ~~due to the construction of the Arrasate ring road, the~~
1615 ~~site was discovered~~ ~~the site was discovered due to the construction of the Arrasate ring road~~, and a savage
1616 excavation was carried out (Arrizabalaga, 2000a). Unfortunately, the site was destroyed after that. The
1617 stratigraphic sequence identified nine different levels. The lower Level IX was attributed to the
1618 Châtelperronian, based on the presence of three Châtelperron points. Although there is a lack of human
1619 remains in few Cantabrian Châtelperronian sites, recent research has suggested that this techno-complex
1620 was produced by Neanderthals (Maroto et al., 2012; Rios-Garaizar et al., 2022). Level VII marks the
1621 beginning of the Aurignacian sequence, likely Proto-Aurignacian, with a lithic assemblage dominated by
1622 Dufour bladelets (Arrizabalaga, 2000a). Levels VI, V, and IV contain lithic assemblages that suggested an
1623 Early Aurignacian attribution (Arrizabalaga, 2000b; Arrizabalaga et al., 2009). This site is significant because
1624 it is one of the few sites with Châtelperronian assemblages and with both Proto-Aurignacian and Early
1625 Aurignacian separated (Arrizabalaga et al., 2009).

1626 Initial radiocarbon dates were inconsistent with the stratigraphy of the site and much more recent than
1627 expected for the Early Upper Paleolithic (Arrizabalaga, 2000a). This incoherence was determined to be
1628 affected by taphonomic alterations (Wood et al., 2014). Later radiocarbon dates undertaken with an
1629 ultrafiltration pre-treatment provided a new regional framework for the regional Early Upper Paleolithic
1630 (Wood et al., 2014). The Châtelperronian layer ~~IX inf~~ is dated to 38,100±900 uncal BP (OxA-22562) and
1631 37,400±800 uncal BP (OxA-22560). The Proto-Aurignacian levels cover a period from 36,850±800 uncal
1632 BP (OxA-21766) to 35,250±650 uncal BP (OxA-21793). The three Early Aurignacian levels are dated to
1633 35,100±600 uncal BP (OxA-21778) for level VI, ~ 34,000 uncal BP (OxA-21767 and OxA-21779) for level
1634 V, and ~ 33,000 BP (OxA-21768 and OxA-21780) for level IV (Arrizabalaga et al., 2009).

1635 Taphonomic studies indicate an alternation in the use of the cave between carnivores and humans, the latter
1636 ~~ones~~ during short occupation periods (Villaluenda et al., 2012; Ríos-Garaizar et al., 2012; Arrizabalaga et
1637 al., 2010). Labeko Koba is considered to have functioned as a natural trap where carnivores, mainly hyenas,
1638 ~~accessed to~~ animal carcasses. At least in the base of Labeko Koba IX, carnivore activity was higher, and
1639 they would have consumed the same prey as humans (Villaluenga et al., 2012). The presence of humans
1640 is linked to strategic use as a campsite associated with a small assemblage of lithic artifacts. The most
1641 consumed species by Châtelperronian groups were red deer, followed by the consumption of large bovids,
1642 equids, and woolly rhinoceros. During the Aurignacian period, there was some stability in human
1643 occupations, although ~~they~~ still alternated with carnivore occupations (Arrizabalaga et al., 2010). Cold-
1644 adapted fauna such as reindeer and woolly rhinoceros were identified in association with the
1645 Châtelperronian. Reindeer ~~were still present during the Aurignacian levels, as well as the woolly mammoth~~
1646 ~~and arctic fox and the woolly mammoth and arctic fox were still present during the Aurignacian levels~~. The
1647 original sampling of the ~~studied~~ teeth ~~studied~~ by this work was performed in the San Sebastian Heritage
1648 Collection headquarters, where the Guipuzcoa archaeological materials were deposited at that time.

1649

1650 **Aitzbitarte III interior** (Rentería, Guipúzcoa, País Vasco)

1651 Aitzbitarte III is an archaeological site located within ~~a the~~ Landarbaso karstic system comprising ~~of~~ nine
1652 caves ~~in Rentería~~ (43.270; -1.8905). The cave is situated 220 m.a.s.l. and is 10 km away from the present-
1653 day coastline. Initial archaeological interventions were carried out at the end of the 19th century by P.M. de
1654 Soraluze (Altuna, 2011). Recent excavations were initially conducted in the deep zone inside the cave
1655 between 1986 and 1993, ~~where the studied tooth was recovered~~, and later focused on the cave entrance
1656 between 1994 and 2002, by J. Altuna, K. Mariezkurrena, and J. Rios-Garaizar (Altuna et al., 2011; 2017).

1657 While the cave's entrance area contains a sequence comprising [possible](#) Mousterian [and](#) Evolved
1658 Aurignacian [and](#) Gravettian [layers](#) [levels](#) (Altuna et al., 2011; 2013), the stratigraphy in the inner cave
1659 presents [8-eight](#) levels: level VIII (some tools with Mousterian features), VII (sterile), VIb, VIa and V (Middle
1660 Gravettian technocomplex with abundance of Noailles burins), IV-II (disturbed archaeological levels) and I
1661 (surface) (Altuna et al., 2017). Levels V have dates of 24,910 uncal BP (I-15208) and 23,230 uncal BP (Ua-
1662 2243); whereas level VI extends from 23,830 ± 345 uncal BP (Ua-2628) and 25,380± 430 uncal BP (Ua-
1663 2244) (Altuna, 1992; Altuna et al., 2017), with a possible outlier dated at 21,130 uncal BP (Ua-1917).

1664 The Gravettian occupation in the inner part of the cave was [originally](#) [initially](#) thought to be more recent than
1665 the ones in the cave entrance. However, it was [not](#) [difficult](#) [easy](#) to correlate the two excavation areas due
1666 to different sedimentation rates. The [rich](#) [abundant](#) human occupations took place during a singular cold
1667 phase in the Middle Gravettian with a specialized paleoeconomy focused on the hunting of *Bos primigenius*
1668 and *Bison priscus* (85% in level VI and 68% in level V), which is unusual in the Cantabrian region mostly
1669 focused on red deer and ibex. Other ungulates present are *Cervus elaphus* and *Rupicapra rupicapra*, and
1670 to a lesser extent *Capra pyrenaica*, *Capreolus capreolus*, *Rangifer tarandus*, and *Equus ferus* (Altuna et al.,
1671 2017; Altuna & Mariezkurrena, 2020). There is a scarce representation of carnivores. The tooth studied was
1672 sampled at the Gordailua Center for Heritage Collections of the Provincial Council of Gipuzkoa.

1673

1674 **El Otero (Secadura, Voto, Cantabria)**

1675 El Otero cave is located in Secadura (Voto) (43.3565; -3.5360), at 129 m.s.a.l and 12 km [straight](#) from the
1676 present-day coastline. [N](#) [near](#) the Matienzo valley in a coastal plain environment covered by meadows and
1677 gentle hills. The discovery was made in 1908 by Lorenzo Sierra. The site was excavated in 1963 by J.
1678 Gonzalez Echegaray and M.A. García Guinea, in two different sectors (Sala I and Sala II) with an equivalent
1679 stratigraphic sequence (González Echegaray, 1966). [A total of a](#) [Nine](#) levels were identified in Sala I, from
1680 level IX to level I. Levels IX and VIII were [originally](#) [initially](#) related to the "Aurignacian-Mousterian, based
1681 on lithics assemblages with a combination of both technocomplex features. The overlying levels VI-IV were
1682 separated by a speleothem crust (level VII) and were initially related to Aurignacian, due to the presence of
1683 end-scrapers, bone points, blades, or burins on truncation (Freeman, 1964; Rios-Garaizar, 2013). Also,
1684 perforated deer, ibex, and fox teeth were found in levels V and IV. This site lacked chronological dating
1685 methods, until a selection of material from levels VI, V and IV revealed a difference [in](#) chrono-cultural
1686 attribution (Marín-Arroyo et al., 2018). Radiocarbon results yielded younger dates for such a cultural
1687 attribution and [showed](#) significant stratigraphic inconsistency. Level VI gave a result of 12,415±55 (OxA-
1688 32585), two dates in Level V are 12,340±55 (OxA-32509) and 10,585±50 (OxA-32510), and a date in Level
1689 IV is 15,990±80 (OxA-32508). All these results fall into the range of the Late Upper Paleolithic (Magdalenian-
1690 Azilian initially identified in levels III-I), eliminating attribution of these levels to the Aurignacian, despite the
1691 presence of apparently characteristic artefacts. [Further assessments of archaeological materials will be](#)
1692 [needed](#).

1693 Red deer dominate the assemblage, except for level IV where horses are more abundant. Wild boar, roe
1694 deer, and ibex are also present, but large bovids are relatively rare (González Echegaray, 1966). Level IV
1695 is the richest and most anthropogenic level, with evidence of butchering in red deer (captured in winter and
1696 early summer) and chamois (in autumn). The formation of this level involved humans and carnivores, and
1697 although certain data may suggest an anthropogenic predominance, the limited sample analyzed
1698 taphonomically and the pre-selection of preserved pieces do not allow for a definitive conclusion (Yravedra
1699 & Gómez-Castanedo, 2010). The material included in this work is curated at the Museo de Prehistoria y
1700 Arqueología de Cantabria (MUPAC, Santander).

1701

1702 **A2. Mediterranean sites**

1703 **Terrasses de la Riera dels Canyars (Gavà, Barcelona, Cataluña)**

1704 Terrasses de la Riera dels Canyars (henceforth, Canyars) is an open-air site located near Gavà (Barcelona)
1705 (41.2961;1.9797), at 28 m.s.a.l and 3 km straight from the present-day coastline. The site lies on a fluvial
1706 terrace at the confluence of Riera dels Canyars, a torrential stream between Garraf Massif, Llobregat delta
1707 and Riera de Can Llong (Daura et al., 2013). Archaeo-paleontological remains were discovered during
1708 quarries activities in 2005 and was complete excavated on 2007 by the *Grup de Recerca del Quaternari*
1709 (Daura and Sanz, 2006; Daura et al., 2013). This intervention determined nine lithological units. The
1710 paleontological and archaeological remains come exclusively from one unit, the middle lithic unit (MLU),
1711 and specifically from layer I. The MLU is composed of coarse sandy clays and gravels, filling a paleochannel
1712 network named lower detrital unit (LDU) (Daura et al., 2013). Five radiocarbon dates were obtained on
1713 charcoals from layer I, which yield statistically consistent ages from 33,800 ±350 uncal BP to 34,900 ±340
1714 uncal BP, which results in mean age of 39,600 cal BP (from 37,405 to 40,916 cal BP) (Daura et al., 2013).

1715 The layer I of the site has yielded a rich faunal assemblage, consisting of over 5,000 remains. Among the
1716 herbivores, the most common species found are *Equus ferus*, *Bos primigenius*, *Equus hydruntinus*, and
1717 *Cervus elaphus* (Daura et al., 2013; Sanz-Royo et al., 2020). *Capra* sp. and *Sus scrofa* are also present,
1718 although in lower frequencies. The carnivores found at the site are also noteworthy, with *Crocuta crocuta*
1719 and *Lynx pardinus* being the most frequent. Presence of cold-adapted fauna associated to stepped
1720 environments is recorded, such as cf. *Mammuthus* sp., *Coelodonta antiquitatis*, and *Equus hydruntinus*.
1721 Small mammal analysis, pollen, and use-wear analysis have provided further evidence that a steppe-
1722 dominated landscape surrounded the Canyars site, supporting a correlation with the Heinrich Event 4, in
1723 coherence with the chronology obtained for the layer (López-García et al. 2013; 2023; Rivals et al., 2017).
1724 However, the presence of woodland is also attested by forest taxa within charcoal and pollen assemblages
1725 (Daura et al., 2013).

1726 Taphonomic study is ongoing. But several evidences point that hyenas have played an important role in the
1727 accumulation of the faunal assemblage (Daura et al., 2013; Jimenez et al. 2019). However, sporadic human
1728 presence is documented by few human modifications found in faunal remains (cutmarks and fire alterations).
1729 Although the paucity of the lithic assemblage in the site, it shows a clear attribution to Upper Palaeolithic
1730 technocomplex, most likely the Early Aurignacian (Daura et al., 2013). Recently, it was documented a
1731 perforated bone fragment, which has been identified as a perforated board for leather production (Doyon et
1732 al., 2023). All teeth included in this work were sampled in *Laboratori de la Guixera* (Ajuntament de
1733 Casteldefels) where the material is stored.

1913 **Appendix D. Inverse Modelling: Methodological Details and Models**

1914 The intratooth $\delta^{18}\text{O}$ profiles presented in this study were obtained through the application of inverse
1915 modelling, –using an adapted version of the code published in reference (Passey et al., 2005b). This
1916 modeling approach allowed for the correction of the damping effect and the reconstruction of the original
1917 $\delta^{18}\text{O}$ input time series. The model reproduces the temporal delay between $\delta^{18}\text{O}$ changes in the
1918 animal's input and their manifestation in tooth enamel, exhibiting a consistent x-direction delay in the
1919 modelled $\delta^{18}\text{O}$ curve relative to the enamel $\delta^{18}\text{O}$ input time series. The model utilizes different species-
1920 specific parameters related to enamel formation, which vary between bovines and equids. These parameters
1921 have been established based on previous studies (Bendrey et al., 2015; Zazzo et al., 2012; Passey and
1922 Cerling, 2002; Kohn, 2004; Blumenthal et al., 2014). For *Bos/Bison* sp., the initial mineral content of enamel
1923 is fixed at 25%, the enamel appositional length is set at 1.5 mm, and the maturation length is 25 mm. For
1924 *Equus* sp., the initial mineral content of enamel is fixed at 22%, the enamel appositional length is set at 6
1925 mm, and the maturation length is 28 mm.

Formatted: Font: Italic

Formatted: Font: Italic

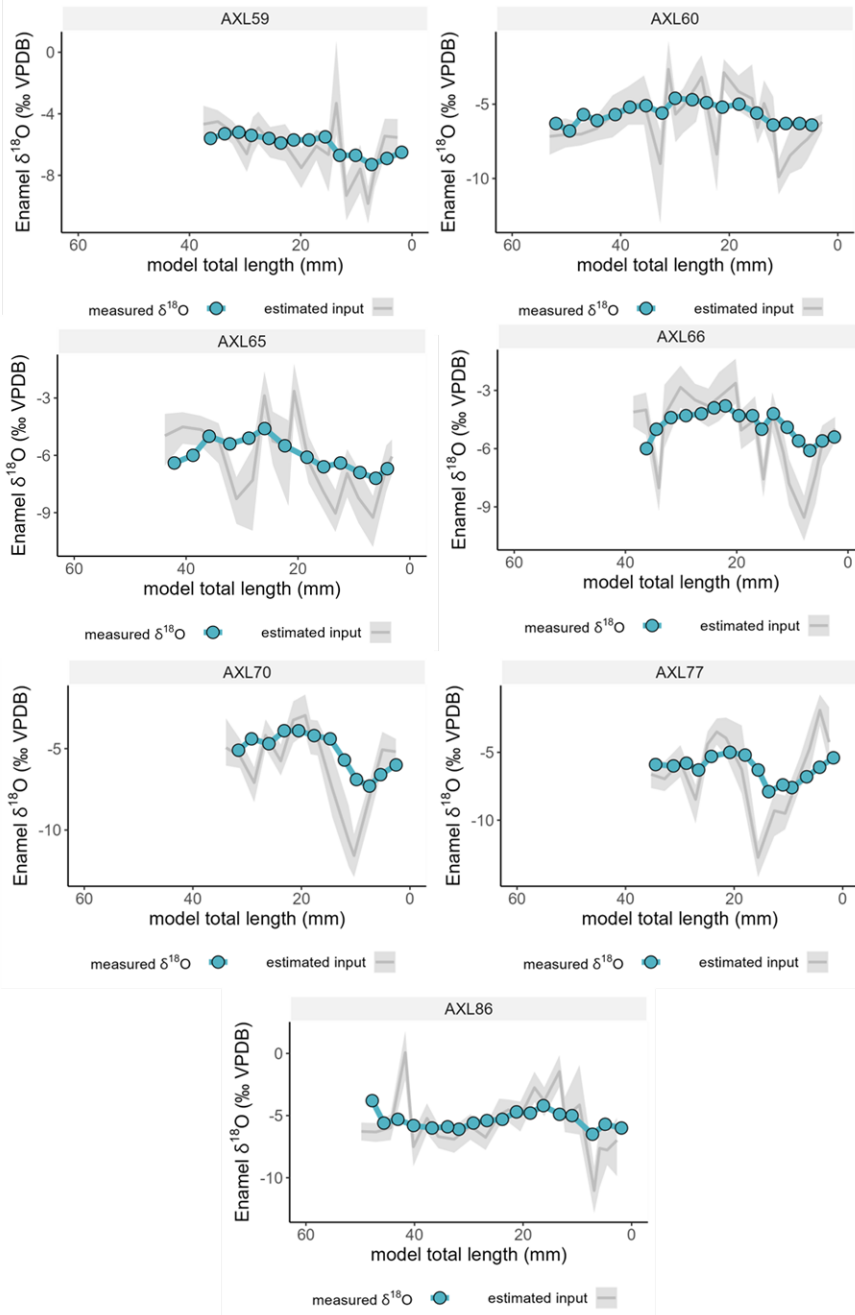

1926 In addition, the model requires other variables related to sampling geometry, as well as error estimates
1927 derived from mass spectrometer measurements. The distance between samples varies for each tooth, but
1928 as a general trend, the sampling depth on the tooth enamel surface in the samples of this study represents
1929 approximately 70% of the total enamel depth. The standard deviation of the measurements obtained from
1930 the mass spectrometer was typically set at 0.12%, taking into account the uncertainty associated with the
1931 standards. Finally, the models require a damping factor that determines the cumulative damping along the
1932 isotopic profile by adjusting the measured error (Emeas) to the prediction error (Epred). In the teeth analysed
1933 in this study, the damping factor ranged from 0.001 to 0.1.

1934 The most likely model solutions were selected, and summer and winter values were extracted from the $\delta^{18}\text{O}$
1935 profiles, considering the original peaks and troughs identified in the unmodelled $\delta^{18}\text{O}$ profile. This approach
1936 was adopted to prevent the introduction of artificial peaks that the model may produce, particularly in teeth
1937 without a distinct sinusoidal shape. Flat and less sinusoidal profile are less suitable for the application of the
1938 model, given its inherent assumption of an approximately sinusoidal form. Non-sinusoidal curves can lead
1939 to complex interpretations in the model outcomes. Consequently, this methodology was not applied to
1940 analysed intratooth $\delta^{13}\text{C}$ profiles, as the examined individuals did not exhibit appreciable seasonal change.
