22 **Abstract**

23 During the Late Pleistocene, stadial and interstadial fluctuations affected vegetation, fauna, and human
24 groups that were forced to cope with these pronounced spatial-temporal climatic and environmental
25 changes. These changes were especially abrupt during the Marine Isotopic Stage (MIS) 3. Here, we
26 reconstruct the climatic trends in northern Iberia considering the stable isotopic composition of ungulate
27 skeletal tissues found in archaeological deposits dated between 80 to 15 ka cal BP. The carbon and oxygen
28 isotopic composition preserved in the carbonate fraction of tooth enamel provides a reliable and high-
29 resolution proxy of the food and water consumed by these animals, which is indirectly related to the local
30 vegetation, environment, and climate, allowing us to estimate paleotemperatures and rainfall intensity. This
31 study presents new isotope data from 44 bovine, equid, and cervid teeth from five archaeological sites in
32 the Vasco-Cantabrian region (El Castillo, Axlor, Labeko Koba, Aitzbitarte III interior and El Otero,) and one
33 in northeastern Iberia (Canyars), where human evidence is attested from the Mousterian to the Magdalenian.
34 The carbon isotope values reflect animals feeding on diverse C3 plants in open environments, and point to
35 differentiated ecological niches for equids and bovines, especially during the Aurignacian in the Vasco-
36 Cantabrian region. Temperature estimations based on oxygen isotopic compositions and rainfall obtained
37 from carbon isotopic compositions indicate colder and more arid conditions than nowadays for the human
38 occupations from the Late Mousterian to the Aurignacian. The contemporary northeastern Iberia site shows
39 slightly lower temperatures related to an arid period when animals mainly graze in open landscapes. In the
40 Vasco-Cantabrian region, during the MIS2, the Gravettian data reflect a landscape opening, whereas the
41 Magdalenian points to warmer (but still arid) conditions.

43 **1. Introduction**

44 Understanding local and regional climatic variability during the Late Pleistocene in southern Europe is crucial
45 for assessing the potential impact of climate on the adaptation and decline of Neanderthals and the
46 subsequent expansion and resilience of Anatomically Modern Humans during the Upper Paleolithic (e.g.,
47 D'Errico and Sánchez Goñi, 2003; Finlayson and Carrión, 2007; Sepulchre et al., 2007; Staubwasser et al.,
48 2018). During the Late Pleistocene, the climatic records demonstrate stadial and interstadial continuous
49 fluctuations during the Marine Isotope Stage 3 (MIS 3, ca. 60-27 ka) and MIS 2 (ca. 27-11 ka). Human
50 groups had to face those episodes, which affected vegetation and fauna to different extents, depending on
51 the region. Northern Iberia is a key study area due to the abundance of well-preserved archaeological caves
52 and rock shelters where, in the last decade, an updated and multidisciplinary approach has been applied to
53 disentangle how changing environmental conditions affected the subsistence dynamics of Middle and Upper
54 Paleolithic hominins. Recent chronological, technological, subsistence studies and ecological
55 reconstructions are revealing a more complex regional panorama than previously known (e.g., Sánchez
56 Goñi, 2020; Vidal-Cordasco et al., 2022; 2023; Timmermann, 2020; Klein et al., 2023).

57 The Vasco-Cantabrian region, located in northwestern Iberia, is subject to the influence of Atlantic climatic
58 conditions, where recently has been evaluated the impact of the glacial-interglacial oscillations during MIS3
59 (Vidal-Cordasco et al., 2022). Modelling of traditional environmental proxies (small vertebrates and pollen)
60 associated to archaeo-paleontological deposits show a progressive shift in the climatic conditions with
61 decreasing temperatures and rainfall levels detected during the late Mousterian (Fernández-García et al.,
62 2023). Ecological alterations have been observed in large mammals, such as niche partitioning between
63 horses and cervids (Jones et al., 2018), a decrease in the available biomass for secondary consumers, and
64 consequently, a reduction in the ungulate carrying capacity ((Jones et al., 2018; Vidal-Cordasco et al., 2022).
65 Cold and arid conditions are observed during the Aurignacian and the Gravettian until the onset of MIS2.
66 Afterwards, during the Last Glacial Maximum (LGM, 23-19 ka), the global climatic deterioration associated
67 with this glacial phase results in colder and more arid conditions in the region, with a predominance of open
68 landscapes. However, this region still provided resources for human survival acting as a refugia with more
69 humid conditions in comparison to the Mediterranean area (Cascalheira et al., 2021; Fagoaga, 2014;
70 Fernández-García et al., 2023; Garcia-Ibaibarriaga et al., 2019a; Lécuyer et al., 2021; Posth et al., 2023).
71 By the end of the LGM, a climate amelioration and a moderate expansion of the deciduous forest are
72 documented from the late Solutrean through the Magdalenian (Garcia-Ibaibarriaga et al., 2019a; Jones et
73 al., 2021).

74 In contrast, northeastern Iberia is influenced by the Mediterranean climate. The MIS 3 human settlement in
75 this region have been linked to cooler temperatures and with higher rainfall, compared to the present, but
76 with climatic fluctuations less pronounced compared to the Vasco-Cantabrian region (López-García et al.,
77 2014; Fernández-García et al., 2020; Vidal-Cordasco et al., 2022). Archaeobotanical and small vertebrate
78 evidence indicate relatively stable climatic conditions, but also suggest the persistence of open forests
79 during the Middle to Upper Paleolithic transition, as found in northwestern Iberia (Allué et al., 2018; Ochando
80 et al., 2021). However, certain archaeological records indicate specific climatic episodes, such as increased
81 aridity and landscape opening during Heinrich Events-Stadials -4 and 5 (e.g., Álvarez-Lao et al., 2017; Daura
82 et al., 2013; López-García et al., 2022; Ruffé et al., 2018).

83 These multi-proxy studies have significantly expanded our understanding of the environmental evolution in
84 Iberia, alongside proxies derived from marine core records in Iberia margins (Fourcade et al., 2022; Martrat
85 et al., 2004; Naughton et al., 2007; Roucoux et al., 2001; Sánchez-Goñi et al., 1999, 2009) and other regional
86 paleoclimatic records sourced from local natural deposits (e.g., Pérez-Mejías et al., 2019; Moreno et al.,
87 2010, 2012; González-Sampériz et al., 2020; Ballesteros et al., 2020). However, the availability of proxies
88 enabling the direct connections between these environmental shifts and human activities remains limited.

89 In this study, we investigate the palaeoecological and palaeoenvironmental dynamics in northern Iberia
90 during the late Middle and Upper Paleolithic by measuring the carbon and oxygen isotopic composition of
91 biapatite carbonates ($\delta^{13}\text{C}_{\text{carb}}/\delta^{18}\text{O}_{\text{carb}}$) preserved in archaeological mammal teeth. These analyses provide
92 high-resolution snapshots of ecological information from animals accumulated during human occupations at

93 the caves. Tooth enamel forms incrementally and does not biologically remodel (Kohn, 2004; Passey and
94 Cerling, 2002), in contrast to other bodily tissues such as bone, which implies that the isotope values
95 measured on them reflect the animal diet and water sources consumed during its mineralisation, around
96 one to two years of life for the species included in our study (bovids, equids, cervids)(e.g., Hoppe et al.,
97 2004; Pederzani and Britton, 2019; Ambrose and Norr, 1993; Luz et al., 1984). The preserved carbon
98 isotope composition relies on animal dietary choices reflecting mainly the type of plant consumed (C3/C4),
99 exposition to light and humidity levels. Otherwise, the oxygen isotope composition reflects mainly the
100 environmental water consumed by animals, directly by drinking or through diet, which reflects isotopic
101 information derived from water sources as well as changes in climatic conditions. Both indirectly provide
102 information on the vegetation and climate that allows estimating past temperatures, rainfall, and moisture
103 on a sub-annual scale, returning isotopic data of the foraging areas where animals were feeding during teeth
104 formation.

105 By analysing the stable isotopic composition of 44 ungulate teeth obtained from 15 archaeological levels
106 directly associated with human occupation, including El Castillo, Axlor, Labeko Koba, Aitzbitarte III interior
107 and El Otero in northwestern Iberia, and Terrasses de la Riera dels Canyars in northeastern Iberia, this
108 study presents novel insights into local and regional environmental and climatic trends associated to human
109 presence during the Late Pleistocene (Fig.1; Fig.2; Appendix A). Specifically, it focuses on the Middle to
110 Upper Paleolithic transition in both areas and the post-LGM period in the Vasco-Cantabrian region.

111 The main objectives of this work are: 1) to assess how regional environmental conditions, including changes
112 in moisture and vegetation cover, but also temperatures and rainfall, are recorded in the stable isotopic
113 composition of tooth enamel; 2) to characterize animal diet and their ecological niches; 3) to obtain
114 quantitative temperature data to compare with available proxies; 4) to characterise seasonal patterns of
115 animals found in the archaeological sites by identifying winter and summer fluctuations.

116
117 **Figure 1.** Location of the archaeological sites included in this study. From west to east, in the autonomous community of
118 Cantabria, El Castillo, and El Otero; in the Basque Country, Axlor and Aitzbitarte III interior; in Catalonia, Canyars.

119 2. Archaeological sites and sampled material

120 This study selected a total of 44 ungulate teeth including 25 bovines (*Bos primigenius*, *Bison priscus*,
121 *Bos/Bison* sp.), 14 equids (*Equus* sp. and *Equus ferus*), and five cervids (*Cervus elaphus*) originating from
122 five archaeological sites in the Vasco-Cantabrian region (El Castillo, El Otero, Axlor, Labeko Koba,
123 Aitzbitarte III interior) and one in the northeastern area (Terrasses de la Riera dels Canyars, henceforth
124 Canyars). These teeth were recovered from 15 archaeological levels attributed to the following
125 technocomplexes: Mousterian (n=14), Transitional Aurignacian (n=10), Châtelperronian (n=2), Aurignacian
126 (n=12), Gravettian (n=1) and Magdalenian (n=5) (Table 1 and 2). Archaeozoological studies of the
127 archaeological sites are available (synthesis in Marín-Arroyo and Sanz-Royo, 2022; Daura et al., 2013) and
128 most prove that faunal remains were accumulated by human acquisition during the different cultural phases.
129 The isotopic results of equids teeth and other ungulates bone collagen from El Castillo were previously
130 published by Jones et al. (2019) in combination with the stable isotopes of ungulates from the site, as well
131 as the combined bioapatite carbonate and phosphate analyses of bovines from Axlor (Pederzani et al.,
132 2023). A comprehensive description of each archaeological site is provided in Appendix A.

133 [Figure 2.](#) Representation of the duration each archaeological level (dots represent the median values, bars represent 95%
 134 confidence intervals for ^{14}C dates and 68% for ESR and OSL dates) related to techno-complexes in both northwestern (in black)
 135 and northeastern Iberia (in green) and the $\delta^{18}\text{O}$ record from the NGRIP (North Greenland Ice Core Project members, 2004;
 136 Rasmussen et al., 2014). Grey bands indicate Greenland Stadials (GS). Dates from EL Castillo (C14 UF, ESR), El Otero (C14
 137 UF), Axlor (C14 UF, OSL), Labeko Koba (C14 UF), Aitzbitarte III-interior (C14 AMS) and Canyars (C14 UF, ABA, ABOx-SC) are
 138 shown in Appendix B and C.
 139

140 [Figure 2.](#) Representation of the duration each archaeological level (dots represent the median values, bars represent 95%
 141 confidence intervals for ^{14}C dates and 68% for ESR and OSL dates) related to techno-complexes in both northwestern (in black)
 142 and northeastern Iberia (in green) and the $\delta^{18}\text{O}$ record from the NGRIP (North Greenland Ice Core Project members, 2004;
 143 Rasmussen et al., 2014). Grey bands indicate Greenland Stadials (GS). Detailed information on OSL, ESR and ^{14}C dates, along
 144 with ^{14}C calibration, are shown in Appendix B and C.

145 3. Methods

146 3.1 Methods: Dating methods

147 Individual Bayesian age models were built for Canyars, El Castillo, Labeko Koba and Aitzbitarte III interior
 148 based on radiocarbon dates (AMS UF and non-UF, ABOx-SC and ABA pretreatments on bones and
 149 charcoal remains) using OxCal4.4 software (Ramsey, 2009), considering the INTCAL20 calibration curve
 150 (Reimer et al., 2020) (Appendix C). The Bayesian model enables the modification of the calibrated
 151 Probability Distribution Function (PDF) of individual dates based on the existing relative stratigraphic
 152 and other relative age information. A resolution of 20 years was assumed, being a reasonable balance between
 153 required accuracy and computational costs. An order function in the OxCal was used to calculate the
 154 probability that one PDF predated another, providing information to assess synchronicity and temporal
 155 overlap of individual archaeological levels and cultural phases in each of the four separate sites modelled.
 156 Dates were organised into a 'Sequence,' and chronological information for each level was grouped into a
 157 single 'Phase' with start and end 'boundaries' to bracket each archaeological level. The interval between the
 158 start of each level and its end provided the duration of each level. In all cases, convergence was greater
 159 than 95%. CQL codes, individual Bayesian models and modelled dates per site are reported in Appendix C.

160 No chronological models were built for El Otero because only a single date was obtained for level IV and El
 161 Castillo levels 20E and 21 (ESR dated) and Axlor levels III, IV and VI (OSL dated) because dates go beyond
 162 the limit of the radiocarbon. To show the duration of these levels in combination with the other sites and
 163 levels, each of these dates was estimated by adding and subtracting the sigma (68% Confidence Interval)
 164 from the uncalibrated date. In this way, we estimated the duration of these levels to be beyond 55 ka cal
 165 BP.

166 3.2 Tooth sampling

167 All teeth included were sequentially sampled to reconstruct the complete $\delta^{18}\text{O}_{\text{carb}}$ and $\delta^{13}\text{C}_{\text{carb}}$ intratooth
 168 profiles based on enamel carbonate bioapatite. Intratooth sequential sampling was applied to the second
 169 and third molars and third and fourth premolars. Bovine and horse teeth sampled exceeded 3-4 cm of crown
 170 height to ensure that at least a one-year isotopic record of animal life was obtained (Britton et al., 2019;
 171 Hoppe et al., 2004). Samples were taken perpendicular to the growth axis on the tooth where the enamel
 172 was best preserved, avoiding, whenever possible taphonomic alterations such as cracks or postdepositional
 173 damages. Samples were performed in the buccal face for the lower teeth and the lingual part for the upper
 174 ones. The outermost enamel surface was abraded to remove the superficial enamel, calculus, cementum,
 175 or concretions adhering to the surface to avoid contaminations. The sequential sampling consisted of
 176 straight strips (ca. 8 x 1.5 x 1 mm) covering the width of the selected lobe, approximately every 2-3 mm,
 177 from the crown to the Enamel-Root-Junction (ERJ). The sample depth covered around 75% of the enamel
 178 depth, and dentine inclusion was avoided. A low-revolution variable-speed manual drill was used, equipped
 179 with 1 mm diamond-coated drill bits of conical and cylindrical shape. About 10-15mg of enamel powder was
 180 collected in each subsample, generating 693 subsamples for IRMS measurements (see complete intratooth
 181 profiles in Appendix D).

182

Site	Level - Cultural period	Bovines	Horses	Red deer	Teeth	Subsamples

184

185

186 3.3 Sample treatment and stable isotope mass spectrometry

187 Several authors have debated the necessity of chemical pre-treatments to remove organic matter and
 188 secondary carbonates from bioapatite carbonates before stable isotopic analysis. Some chemical
 189 treatments can introduce secondary carbonates, increase carbonate content, and alter the original isotopic

190 signal (Pellegrini and Snoeck, 2016; Snoeck and Pellegrini, 2015). For this reason, in this work, most of the
191 samples were not pretreated except for the equids and cervids samples from Labeko Koba, El Otero and El
192 Castillo that were sampled and pretreated in an earlier phase of the project. The absence of pretreatment
193 can elevate the risk of secondary carbonates (Chesson et al., 2021; France et al., 2020). Nonetheless, any
194 pretreatment method cannot guarantee their complete removal, and the 'side effects' may compromise the
195 final isotopic signal to a greater extent. While variations in pretreatment methods exist among samples in
196 this study, the lack of a universally accepted protocol necessitates careful consideration of any potential
197 isotopic effects resulting from these differences.

198 Pretreatment was followed for above-mentioned samples from fourteen teeth, where around 7 mg of
199 powdered enamel was prepared and pretreated with 3% of sodium hypochlorite (NaOCl) at room
200 temperature for 24 h (0.1 ml/mg sample) and thoroughly rinsed with deionised water, before a reaction with
201 0.1M acetic acid for 4 h (0.1 ml/mg sample) (Balasse et al., 2002; equivalent protocol in Jones et al., 2019).
202 Samples were then thoroughly rinsed, frozen, and freeze-dried. NaOCl is one of the most common agents
203 used for pretreating carbonates and works as a base that removes organic matter by oxidation. Although it
204 is considered one of the most efficient agents for removing organic matter, it can induce the absorption of
205 exogenous carbonates, such as atmospheric CO₂ and secondary carbonates (Pellegrini and Snoeck, 2016;
206 Snoeck and Pellegrini, 2015). It is argued that acetic acid after NaOCl pretreatment can remove exogenous
207 carbonates absorbed during NaOCl application. However, it is unclear if all newly introduced carbonates are
208 finally released and which effect they produce on the original isotopic composition. These samples were
209 analysed in the Godwin Laboratory (Department of Earth Sciences, University of Cambridge). Enamel
210 powder samples were reacted with 100% orthophosphoric acid for 2 h at 70°C in individual vessels in an
211 automated Gasbench interfaced with a Thermo Finnigan MAT253 isotope ratio mass spectrometer. Results
212 were reported in reference to the international standard VPDB and calibrated using the NBS-19 standard
213 (limestone, $\delta^{13}\text{C} = +1.95\text{‰}$ and $\delta^{18}\text{O} = -2.2\text{‰}$; Coplen, 2011) for which the precision is better than 0.08‰
214 for $\delta^{13}\text{C}$ and 0.11‰ for $\delta^{18}\text{O}$.

215 For the non-pre-treated samples, carbon and oxygen stable isotopic ratios were measured using continuous
216 flow-isotope ratio mass spectrometry, specifically a Europa Scientific 20-20 IRMS coupled to a
217 chromatograph, at the Iso-Analytical laboratory in Cheshire, UK. The samples were weighed into clean
218 exetainer tubes after being flushed with 99.995% helium. Phosphoric acid was then added to the samples,
219 and they were allowed to react overnight to ensure the complete conversion of carbonate to CO₂, following
220 the method outlined by Coplen et al. (1983). The reference materials used for VPDB calibration and quality
221 control of the analysis included IA-R022 (calcium carbonate, $\delta^{13}\text{C} = -28.63\text{‰}$, $\delta^{18}\text{O} = -22.69\text{‰}$), NBS-18
222 (carbonatite, $\delta^{13}\text{C} = -5.01\text{‰}$, $\delta^{18}\text{O} = -23.2\text{‰}$), IA-R066 (chalk, $\delta^{13}\text{C} = +2.33\text{‰}$, $\delta^{18}\text{O} = -1.52$). The accepted
223 values of the in-house standards IA-R022 and IA-R066 were obtained by calibrating against IAEA
224 international reference materials, NBS-18 and NBS-19, and NBS-18 and IAEA-CO-1 (Carrara marble, $\delta^{13}\text{C}$
225 = 2.5‰, and $\delta^{18}\text{O} = -2.4\text{‰}$), respectively. Additionally, in-house standards long-term measured were used:
226 ILC1 (calcite, $\delta^{13}\text{C} = 2.13$, $\delta^{18}\text{O} = -3.99\text{‰}$), and Y-02 (calcite, $\delta^{13}\text{C} = 1.48$, $\delta^{18}\text{O} = -9.59\text{‰}$). The analytical
227 precision of quality control standard replicates was better than 0.09‰ for $\delta^{13}\text{C}$ and better than 0.12‰ for
228 $\delta^{18}\text{O}$. The calcium carbonate content test of these samples, ranging between 3.9% and 8.9%, does not
229 indicate a substantial presence of secondary carbonates, considering Chesson et al. (2021). Additionally,
230 phosphate results on samples from Axlor showed $\delta^{18}\text{O}_{\text{carb}} - \delta^{18}\text{O}_{\text{phos}}$ offsets within the expected range for well-
231 preserved samples (Pederzani et al., 2023).

232 3.4 Carbon stable isotopic compositions as environmental and ecological tracers

233 To unravel animal diet and compare the different species, in standardised terms, it is necessary to consider
234 the enrichment factor (ϵ^*) between $\delta^{13}\text{C}$ obtained by the animal on its diet ($\delta^{13}\text{C}_{\text{diet}}$) and $\delta^{13}\text{C}$ recorded on

235 enamel carbonates ($\delta^{13}\text{C}_{\text{carb}}$) (Bocherens, 2003; Cerling and Harris, 1999). The ϵ^* estimated for large
 236 ruminant mammals results in an offset of around 14.1‰ between diet and dental enamel, commonly applied
 237 to medium-sized herbivores. However, it is well-known that this offset varies between species, considering
 238 animals' different physiological parameters. Recently, a formal model to predict species-specific diet-
 239 consumer isotopic offsets has been proposed, which uses body mass (BM) and digestive physiology as the
 240 main factors that regulate the ϵ^* (Tejada-Lara et al., 2018). This model proposes the following prediction
 241 equations for ruminant or foregut fermenters (Equation 1: Eq.1) and hindgut fermenters (Eq. 2):

242 (Eq. 1) $\epsilon^* = 2.34 + 0.05 (\text{BM})$ [$r^2=0.78$; p-value=0.008]

243 (Eq. 2) $\epsilon^* = 2.42 + 0.032 (\text{BM})$ [$r^2=0.74$; p-value=0.003]

244 This work compares species with different digestive physiology, ruminants for bovines and cervids, and non-
 245 ruminants for equids. The ϵ^* value was adjusted for each animal to avoid bias from digestive physiology
 246 when comparing these species. The following enrichment factors have been used: 14.6‰ for *Bos taurus*
 247 (Passey et al., 2005a), 13.7‰ for *Equus caballus* (Cerling and Harris, 1999), and 13.2‰ for *Cervus elaphus*
 248 (Merceron et al. (2021) following (Eq. 1) for ruminants with a mean body mass of 125 kg.

249 In body tissues, carbon isotopic composition is considered a combination of diet (understood as consumed
 250 food), environment openness (and associated exposure to light), and the amount of precipitation. Assuming
 251 that $\delta^{13}\text{C}$ of past vegetation is close to $\delta^{13}\text{C}_{\text{diet}}$ of ungulates, Lécuyer et al. (2021) proposed to estimate Mean
 252 Annual Precipitations (MAP) from $\delta^{13}\text{C}_{\text{carb}}$, derived from diets based on C3 plants. After transforming $\delta^{13}\text{C}_{\text{carb}}$
 253 to $\delta^{13}\text{C}_{\text{diet}}$ using the enrichment factors established above, this work suggested transforming this value to
 254 $\delta^{13}\text{C}$ from vegetation ($\delta^{13}\text{C}_{\text{leaf}}$). However, the isotopic composition of animals' diet may not directly reflect
 255 vegetation cover, but rather the food preference of the animal and this approach should be discussed
 256 alongside other environmental data.

257 The MAP estimation is based on least square regression developed by Rey et al. (2013) and based on Kohn
 258 (2010) dataset (Eq.4), which requires first to estimate the $\delta^{13}\text{C}_{\text{leaf}}$ (Eq. 3). The $\delta^{13}\text{C}$ values of atmospheric
 259 CO_2 ($\delta^{13}\text{C}_{\text{atm}}$) are fixed in -7‰ (Lécuyer et al., 2021; Leuenberger et al., 1992; Schmitt et al., 2012).
 260 Atmospheric CO_2 levels have varied throughout the Late Pleistocene, with $\delta^{13}\text{C}_{\text{atm}}$ range between -7 to -
 261 6.4‰ (Eggleson et al., 2016), favouring an age-specific correction approach. However, maintaining general
 262 corrections is preferred considering the chronological uncertainty of the studied levels.

263 (Eq.3) $\delta^{13}\text{C}_{\text{leaf}} (\text{VPDB}) = (\delta^{13}\text{C}_{\text{atm}} - \delta^{13}\text{C}_{\text{diet}}) / [1 + (\delta^{13}\text{C}_{\text{diet}} / 1000)]$

264
 265 (Eq.4) $\text{Log}_1(\text{MAP}+300) = 0.092(\pm 0.004) \times \delta^{13}\text{C}_{\text{leaf}} + 1.148(\pm 0.074)$

266
 267 Additionally, Lécuyer et al. (2021) equation also accounts for the pCO_2 effect on $\delta^{13}\text{C}_{\text{leaf}}$ estimation, which
 268 is expected to result in an offset of +1‰ from current levels (considering that pCO_2 was lower than that
 269 experienced after the deglaciation period). If this correction was not applied, MAP results could be
 270 underestimated by -150mm. In agreement with Lécuyer et al. (2021) appreciation, these MAP estimations
 271 are a preliminary approximation and should be cross-validated with other environmental proxies. The
 272 associated uncertainties range from ± 100 to 200 mm, influencing the interpretation of the final values.

273 3.5 Oxygen stable isotope compositions as environmental tracers

274 Stable oxygen isotopes from meteoric water (mainly derived from rainfall) strongly correlate with mean air
 275 temperatures in mid to high latitudes (Dansgaard, 1964; Rozanski et al., 1992) on a regional-to-local scale.
 276 Obligate drinkers, like bovines and horses, acquire this water and record its isotopic composition in their
 277 teeth and bones with a fixed but species-specific offset (Pederzani and Britton, 2019). Considering this two-

278 step relationship, past climatic conditions can be estimated. However, most of the temperature
279 reconstructions based on $\delta^{18}\text{O}$ have considered the $\delta^{18}\text{O}$ from the phosphate fraction of bioapatite enamel
280 ($\delta^{18}\text{O}_{\text{phos}}$) to build linear correlations between tooth enamel and drinking water $\delta^{18}\text{O}$ and obtain climatic
281 information. For this reason, the $\delta^{18}\text{O}_{\text{carb}}$ values obtained in this work were converted into $\delta^{18}\text{O}_{\text{phos}}$. To do so,
282 first, to express in VSMOW notation, the $\delta^{18}\text{O}_{\text{carb}}$ was corrected using the following correlation (Brand et al.,
283 2014; Coplen et al., 1983):

$$284 \quad (\text{Eq.5}) \delta^{18}\text{O}_{\text{carb}} (\text{VSMOW}) = 1.0309 \times \delta^{18}\text{O}_{\text{carb}} (\text{VPDB}) + 30.91$$

285 Second, considering the relationship existent in tooth enamel between the carbonate and phosphate fraction
286 (Iacumin et al., 1996; Pellegrini et al., 2011), from a compilation of the existent bibliography of modern
287 animals measurements (Bryant et al., 1996; Pellegrini et al., 2011; Trayler and Kohn, 2017), Pederzani et
288 al. (2023) proposed the following correlation:

$$289 \quad (\text{Eq.6}) \delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) = 0.941 \times c (\text{VSMOW}) - 7.16$$

290 Once the isotopic information is expressed in $\delta^{18}\text{O}_{\text{phos}}$ (VSMOW), we can estimate the $\delta^{18}\text{O}$ on meteoric
291 waters ($\delta^{18}\text{O}_{\text{mw}}$). It is known that different physiological factors will condition how oxygen isotope composition
292 is fixed in each mammalian group. Thus, the correlations are usually species-specific and developed
293 considering the physiology of each animal group. The obligate drinkers heavily rely on consuming large
294 amounts of liquid drinking water, being the relative contribution of water from plants negligible and then
295 minimizing the possible impact of isotopic enrichment through evapotranspiration in plants (Hoppe, 2006;
296 Maloïy, 1973; Pederzani and Britton, 2019). However, certain types of drinking behaviours can impact δ
297 ^{18}O , such as systematic consumption of certain highly buffered water sources (rivers or lakes), can
298 significantly attenuate the final signal recorded. The correlation employed by this work relies on recent data
299 compilations (Pederzani et al., 2021b, 2023). In the case of horses (Eq. 7), it has been considered the data
300 combination of Blumenthal et al. (2019); Chillón et al. (1994); Bryant et al., 1994; Delgado Huertas et al.,
301 1995), whereas for bovines (Eq. 8) the data from D'Angela and Longinelli (1990) and Hoppe (2006) have
302 been put together in Eq. 4. To estimate $\delta^{18}\text{O}_{\text{mw}}$ from red deer remains, we selected D'Angela and Longinelli
303 (1990) correlation (Eq. 9):

$$304 \quad (\text{Eq.7}) \delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 22.14) / 0.62$$

$$305 \quad (\text{Eq.8}) \delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 22.36) / 0.78$$

$$306 \quad (\text{Eq.9}) \delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 24.39) / 0.91$$

307 Finally, paleotemperatures estimations from $\delta^{18}\text{O}_{\text{mw}}$ are typically approached using a geographically
308 adjusted linear regression, which can vary from precise adjustments (aimed at reducing errors) to broader
309 geographical adjustments that encompass more variability but are less precise (e.g., Pryor et al., 2014;
310 Skrzypek et al., 2011; Tütken et al., 2007). In this work, temperatures were calculated considering the linear
311 regression model relating $\delta^{18}\text{O}_{\text{mw}}$ and air temperatures proposed by Pederzani et al. (2021) based on
312 monthly climatic records (monthly mean $\delta^{18}\text{O}_{\text{mw}}$ and monthly mean air temperatures), from Western,
313 Southern and Central Europe stations from the Global Network of Isotopes in Precipitation (IAEA/ WMO,
314 2020). Considering current IAEA data sets from northern Iberia, there is a strong positive relationship
315 between $\delta^{18}\text{O}_{\text{mw}}$ and annual or monthly temperatures (Moreno et al., 2021). However, it is known that Iberia
316 is under a mixed influence between Atlantic and Mediterranean moisture sources that affects the isotopic
317 composition of rainfall (Araguas-Araguas and Diaz Teijeiro, 2005; García-Alix et al., 2021; Moreno et al.,
318 2021). Given uncertainties in past atmospheric circulation patterns and the limited availability of reference
319 stations, it was deemed most appropriate to select an equation that extends beyond the borders of Iberia

320 and incorporates higher variability. Different correlations were for mean annual temperature (Eq. 10),
321 summer (Eq. 11), and winter (Eq. 12) temperatures (T):

322 (Eq.10) $\delta^{18}\text{O}_{\text{mw}}$ (VSMOW) = (0.50 x T) - 13.64

323 (Eq.11) $\delta^{18}\text{O}_{\text{mw}}$ (VSMOW) = (0.46 x T) - 14.70

324 (Eq.12) $\delta^{18}\text{O}_{\text{mw}}$ (VSMOW) = (0.52 x T) - 11.26

325 Nonetheless, oscillations between glacial and interglacial conditions in the past have influenced global ice
326 volume and sea level fluctuations (Dansgaard, 1964; Shackleton, 1987), impacting seawater oxygen isotope
327 composition and the surface hydrological cycle on a worldwide scale, including $\delta^{18}\text{O}_{\text{mw}}$ (Schrag et al., 2002).
328 Prior studies have used sea level information to correct $\delta^{18}\text{O}_{\text{mw}}$ (e.g., Fernández-García et al., 2019; Schrag
329 et al., 2002). Given the chronological uncertainty in the studied levels, a general correction was applied to
330 $\delta^{18}\text{O}_{\text{mw}}$ before temperature estimations, following Fernández-García et al. (2020) approach. Considering the
331 mean sea level descent for the MIS 3 period (50 meters below present-day sea level)(Chappell and
332 Shackleton, 1986), this may have contributed to a potential increase in the global $\delta^{18}\text{O}_{\text{mw}}$ value by $\approx 0.5\%$,
333 inferring a bias in calculated air temperatures of $\approx 1^\circ\text{C}$.

334 Due to the uncertainties incurred from converting stable isotope measurements to palaeotemperature, the
335 final estimations in this work should be considered exploratory and as a method of standardisation to make
336 results comparable among different sites, species, and other non-isotopic palaeoclimatic records. In these
337 estimations, the associated error from converting $\delta^{18}\text{O}_{\text{phos}}$ to MAT is enlarged by the uncertainty derived
338 from the transformation of $\delta^{18}\text{O}_{\text{carb}}$ (VPDB) to $\delta^{18}\text{O}_{\text{phos}}$ (VSMOW) (see Pryor et al., 2014; Skrzypek et al.,
339 2016 for further discussion). However, Pryor et al. (2014) and Pederzani et al. (2023) concluded that the
340 impact of this conversion is negligible compared to the error propagation in subsequent calibrations used
341 for temperature estimations from $\delta^{18}\text{O}_{\text{phos}}$. These associated errors were quantified following the
342 methodology outlined by Pryor et al. (2014) (Appendix B).

343 3.6 Inverse modelling applied to intratooth profiles

344 Intratooth profiles frequently provide a time-averaged signal compared to the input isotopic signal ($\delta^{13}\text{C}/$
345 $\delta^{18}\text{O}_{\text{carb}}$) during enamel formation (Passey et al., 2005b). This signal attenuation is caused by time-averaging
346 effects incurred through the extended nature of amelogenesis and tooth formation, and through the sampling
347 strategy. During mineralisation, the maturation zone, which is time-averaged, often affects a large portion of
348 the crown height and might affect the temporal resolution of the input signal of the sample taken. To obtain
349 climatically informative seasonal information on the analysed teeth, the inverse modelling method proposed
350 by (Passey et al. (2005b) is applied in this work. This method computationally estimates the time-averaging
351 effects of sampling and tooth formation to obtain the original amplitude of the isotopic input signal more
352 accurately, thus, to summer and winter extremes (Appendix E). This method considers parameters based
353 on the amelogenesis trends of each species and sampling geometry, which are critical for a meaningful
354 interpretation of intratooth isotope profiles. The model also estimates the error derived from the sampling
355 uncertainty and the mass spectrometer measurements to evaluate the data's reproducibility and precision.
356 This method was initially developed for continuously growing teeth, taking into account a constant growth
357 rate within a linear maturation model, with a progressive time-average increment as sampling advances
358 along the teeth profile. The species studied in this research exhibit non-linear tooth enamel formation,
359 particularly in later-forming molars (Bendrey et al., 2015; Blumenthal et al., 2014; Kohn, 2004; Passey and
360 Cerling, 2002; Zazzo et al., 2012). Although the model mentioned above is not ideal, as it does not take into
361 account non-linear enamel formation and specific growth parameters for the species included are unknown,
362 it is the best estimation based on the current state of the field and remains widely used (Pederzani et al.,
363 2021a, b, 2023). Flat and less sinusoidal profiles are less suitable for the application of the model, given its

364 inherent assumption of an approximately sinusoidal form. Therefore, we chose not to apply this methodology
365 in the analysis of intratooth $\delta^{13}\text{C}$ profiles, and it is recommended to approach the interpretation of model
366 outcomes for non-sinusoidal $\delta^{18}\text{O}$ curves with caution. Further details on the application of this method can
367 be found in Appendix E.

368 Following Pederzani et al. (2021b), mean annual temperatures (MAT) were deduced from the average of
369 $\delta^{18}\text{O}_{\text{carb}}$ values between summer and winter detected in original sinusoidal intratooth profiles (Appendix D).
370 This work shows that comparable results for annual means can be obtained before and after model
371 application, but doing it beforehand avoids the associated errors induced by the inverse model. To maximize
372 data, in non-sinusoidal teeth profiles, MAT was deduced from the average of all points within a tooth.
373 However, this approach is less reliable when complete annual cycles are not recorded. When possible,
374 summer and winter temperature estimations were derived from the obtained $\delta^{18}\text{O}_{\text{carb}}$ values after inverse
375 modelling application, aiming to identify the corrected seasonal amplitude, which is dampened in the original
376 $\delta^{18}\text{O}_{\text{carb}}$ signal.

377 **3.7 Present-day isotopic and climatic data**

378 Present-day climatic conditions surrounding each site have been considered, allowing an inter-site
379 comparison, essential for compare this study with other regional and global data. Considering current MATs
380 and MAPs, estimated climatic data is expressed in relative terms as MAT and MAP anomalies. Present-day
381 summer and winter temperatures were also considered. Present-day temperatures and precipitation values
382 were obtained from the WorldClim Dataset v2 (Fick and Hijmans, 2017) (Appendix B). This dataset includes
383 the average of bioclimatic variables between 1970-2000 in a set of raster files with a spatial resolution every
384 2.5 minutes. The exact location of the selected archeo-palaeontological sites was used, using geographical
385 coordinates in the projection on modern climatic maps with QGIS software.

386 Present-day $\delta^{18}\text{O}_{\text{mw}}$ values from the analysed sites' areas were obtained using the Online Isotopes in
387 Precipitation Calculator (OIPC Version 3.1 (4/2017); Bowen, 2022) based on datasets collected by the
388 Global Network for Isotopes in Precipitation from the IAEA/WMO (Appendix B).

In northwestern Iberia, specifically in the Vasco-Cantabrian region, the mean $\delta^{13}\text{C}_{\text{carb}}$ values range from -13‰ to -8.9‰, with a mean value of -11‰ (SD = 1.2‰) (Table 2; Table 3). Considering species' different enrichment factors, the $\delta^{13}\text{C}_{\text{carb}}$ were transformed in $\delta^{13}\text{C}_{\text{diet}}$, resulting in mean values that extend from -27‰ to -23.5‰ (Fig. 4). It must be considered that average values may reflect slightly different periods or be affected by seasonal bias because different teeth encompass diverse periods, but it has been verified in our teeth that the variations are limited when the seasonal information of the sequential sampling is incorporated (± 0.2 ; Appendix B). The carbon isotopic composition varies between species. The bovines have generally higher mean $\delta^{13}\text{C}_{\text{carb}}$ (from -12.4‰ to -8.9‰) than the horses (from -12.6‰ to -11.3‰), whereas the red deer fall within the horses' range (from -13‰ to -11.3‰). Average values of $\delta^{18}\text{O}_{\text{carb}}$ in all Vasco-Cantabrian individuals extend between -7.2‰ and -3.3‰ (mean = -5.5‰; SD = 0.8‰). When transformed to $\delta^{18}\text{O}$ expected from meteoric waters ($\delta^{18}\text{O}_{\text{mw}}$), with species-adapted correlations, the $\delta^{18}\text{O}_{\text{mw}}$ values range from -10.6‰ to -5.5‰. Less clear patterns in $\delta^{18}\text{O}_{\text{carb}}$ are observed between bovines and horses, with mean values of -5.7‰ and -5.2‰, respectively. In northeastern Iberia, the site of Canyars, both species have relatively high $\delta^{18}\text{O}_{\text{carb}}$ values that fall inside the range of variation observed in the Cantabria region, between -5.5‰ and -3.6‰ in bovines and between -4.8‰ and -4.4‰ in horses.

411 **Table 3.** Mean $\delta^{13}\text{C}$ from enamel carbonate ($\delta^{13}\text{C}_{\text{carb}}$) and diet ($\delta^{13}\text{C}_{\text{diet}}$), and $\delta^{18}\text{O}$ from enamel carbonate ($\delta^{18}\text{O}_{\text{carb}}$) and meteoric
412 waters ($\delta^{18}\text{O}_{\text{mw}}$), by species on the Vasco-Cantabrian and northeastern Iberia areas. Max: maximum value; Min: minimum value;
413 SD: standard deviation.

414 4.1 Axlor (Mousterian, ca. 80 ka BP - 50 ka cal BP)

415 A total of seven bovine teeth were included from levels III (n = 4), IV (n = 1), and VI (n = 2) of Axlor cave
416 (Pederzani et al., 2023). The mean $\delta^{13}\text{C}_{\text{carb}}$ range from -9.9‰ to -8.9‰ ($\delta^{13}\text{C}_{\text{diet}}$ = -24.5‰ to -23.5‰);
417 whereas mean $\delta^{18}\text{O}_{\text{carb}}$ values are between -6.2‰ and -4.8‰ ($\delta^{18}\text{O}_{\text{mw}}$ = -8.3‰ and -6.5‰), indicating a
418 range of variation around 1‰ and 1.4‰, respectively (Fig. 3; 4). Considering isotopic compositions by levels,
419 mean $\delta^{13}\text{C}_{\text{carb}}$ decreases from level III to level IV, whereas mean $\delta^{18}\text{O}_{\text{carb}}$ remains stable through the
420 sequence (Table 2; Appendix B). A range between 0.3‰ and 0.5‰ is observed in $\delta^{13}\text{C}_{\text{carb}}$ variation within
421 tooth profiles. Individuals show clear $\delta^{18}\text{O}$ sinusoidal profiles, with peaks and troughs and intratooth ranges
422 from 2.1‰ to 3.4‰. The $\delta^{18}\text{O}_{\text{mw}}$ after inverse modelling intratooth profiles range from -9.1‰ to -7.35‰
423 (Appendix D; E). Mean Annual Temperatures (MATs) oscillated between 9.1°C and 12.6°C (MATAs = -
424 3.1/+0.4°C) (Table 4). From sinusoidal profiles, summer temperatures were extracted from peaks, resulting
425 from 15.4°C to 23.7°C, and winter temperatures from troughs provided values ranging from -7°C to 10.8°C.
426 Mean Annual Precipitation (MAPs), extracted from $\delta^{13}\text{C}_{\text{carb}}$, extend between 204mm and 326mm (MAPAs =
427 -843/-721mm). Based on these estimations, a non-clear climatic trend is observed through these levels.

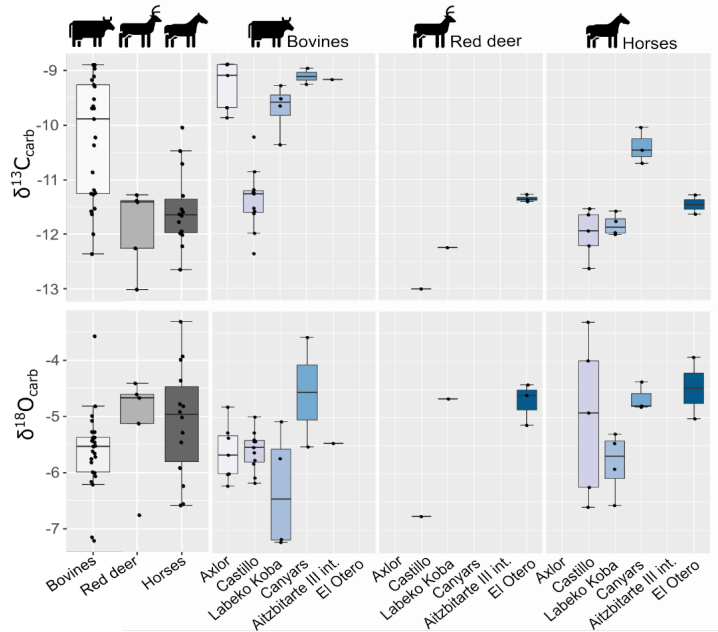

428 4.2 El Castillo (Mousterian and Transitional Aurignacian, 62.5 ka BP – 46.4 ka cal BP)

429

430 From El Castillo, this work includes bovines (n = 11), horses (n = 5), and red deer (n = 1) teeth from the
431 Mousterian (21 and 20E) and the Transitional Aurignacian levels (18B and 18C). The mean $\delta^{13}\text{C}_{\text{carb}}$ values
432 are lower for horses, bovines, and red deer (-13‰ to -10.2‰) than other sites. Between -12.4‰ and -10.2‰
433 for bovines ($\delta^{13}\text{C}_{\text{diet}}$ = -24.6‰ to -25.8‰) and between -12.6‰ and -11.5‰ for horses ($\delta^{13}\text{C}_{\text{diet}}$ = -26.3‰ to
434 -25.2‰) (Fig. 3). The mean $\delta^{18}\text{O}_{\text{carb}}$ values extend from -6.8‰ and -3.3‰. Horses and bovines overlap in
435 their isotopic niche (Fig. 4), mainly due to the notably lower $\delta^{13}\text{C}_{\text{carb}}$ reported by bovines. The mean $\delta^{13}\text{C}_{\text{carb}}$
436 (-13‰) of the single red deer tooth is inside the variation range of bovines and horses but with a lower
437 $\delta^{18}\text{O}_{\text{carb}}$ mean value (-6.8‰). Considering these isotopic compositions by levels, bovine mean $\delta^{13}\text{C}_{\text{diet}}$ values
438 highly increase the variation range from Mousterian levels (20E and 21A) to Transitional Aurignacian levels
439 (18C and 18B). In contrast, horses increase mean $\delta^{13}\text{C}_{\text{diet}}$ values (Fig. 5). Bovine mean $\delta^{18}\text{O}_{\text{mw}}$ values
440 decrease from level 21A to level 18B, while horses from 18B have a large intra-level amplitude.

441 The mean $\delta^{18}\text{O}_{\text{carb}}$ values from horses have a more significant variation (range = 3.3‰) than bovines (range
442 = 2.2‰). All individuals show flat $\delta^{13}\text{C}_{\text{carb}}$ intratooth profiles (<0.4‰), except for red deer (1‰) (Appendix D).
443 Intratooth $\delta^{18}\text{O}_{\text{carb}}$ ranges of individuals are around 1-2‰ for horses and 1-3‰ for bovines. Some of the
444 individuals analyzed do not show non-complete annual cycles. No precise $\delta^{18}\text{O}_{\text{carb}}$ sinusoidal profiles are

445 detected in three teeth; the other six have particularly unclear profiles. After modelling, individual $\delta^{18}\text{O}_{\text{carb}}$
 446 ranges oscillated between 2.7‰ and 7.4‰ (Appendix E). MATs oscillated between 4.6°C and 12.6°C
 447 (MATAs = -8.8°C/-0.9°C), with mean summer temperatures from around 20.5°C and mean winter
 448 temperatures around -1.1°C. MAPs extend between 376mm and 784mm (MAPAs = -656/-248mm) (Table
 449 4). Non-important differences in rainfall estimations based on bovines and equids are noticed, probably
 450 because they feed on similar ecological resources. Diachronic trends are unclear along the sequence but
 451 mean annual and winter temperatures from levels 18C and 18C seem slightly lower. MAPs estimations
 452 oscillated more in the upper levels.

453
 454 **Figure 3.** Distribution of mean carbon ($\delta^{13}\text{C}_{\text{carb}}$) and oxygen ($\delta^{18}\text{O}_{\text{carb}}$) isotopic values of enamel carbonate by species and
 455 archaeological site.

456
457 **Figure 4.** Biplot crossing $\delta^{13}\text{C}$ from diet ($\delta^{13}\text{C}_{\text{diet}}$) and $\delta^{18}\text{O}$ from meteoric waters ($\delta^{18}\text{O}_{\text{mw}}$) by species and archaeological site.

458 **4.3 Labeko Koba (Châtelperronian and Aurignacian, 45.1-36.3 ka cal BP)**

459 This work includes bovines ($n = 4$), horses ($n = 4$), and red deer ($n = 1$) teeth from levels related to
 460 Châtelperronian (IXb inf), ProtoAurignacian (VII), and Aurignacian (VI, V, and IV). Significant differentiation
 461 in mean $\delta^{13}\text{C}_{\text{carb}}$ between bovines and horses is observed, with higher values between -9.3‰ and -10.4‰
 462 in bovines ($\delta^{13}\text{C}_{\text{diet}} = -25\text{‰}$ to -23.8‰) than equids, whose values extend from -12‰ to -11.6‰ ($\delta^{13}\text{C}_{\text{diet}} = -$
 463 25.8‰ to -25.2‰) (Fig. 3;). These horses' values are within the ranges observed from this species in the
 464 region. Red deer have similar $\delta^{13}\text{C}_{\text{carb}}$ values to those of horses ($\delta^{13}\text{C}_{\text{carb}} = -12.3\text{‰}$; $\delta^{13}\text{C}_{\text{diet}} = -25.5\text{‰}$). Mean
 465 $\delta^{18}\text{O}_{\text{carb}}$ values are similar between species from -7.2‰ to -4.7‰ ($\delta^{18}\text{O}_{\text{mw}} = -8.5\text{‰}$ to -6.1‰). However,
 466 bovines have a very high variation within mean $\delta^{18}\text{O}_{\text{carb}}$ values (2.1‰), also reflected in the intratooth
 467 profiles. These $\delta^{18}\text{O}$ values are lower than in other Vasco-Cantabrian sites, especially for two individuals in
 468 levels VII and V (Table 3). Differences in $\delta^{13}\text{C}_{\text{diet}}$ values between bovines and horses result in isotopic niche
 469 differentiation between both species (Fig. 4). The red deer niche is placed within the horses' niche. The
 470 evolution of niche over time cannot be evaluated by levels due to the limited sample. Considering the isotopic
 471 compositions by levels (Fig. 5), both bovines and horses experienced a slight increase in mean $\delta^{13}\text{C}_{\text{diet}}$ from
 472 levels IX inf to IV, from Châtelperronian to Aurignacian. Mean $\delta^{18}\text{O}_{\text{mw}}$ values of bovines decrease from VII
 473 to V, whereas horses increase from IXb inf to VI to decrease from VI to IV.

474 Variability of $\delta^{13}\text{C}_{\text{carb}}$ values in intratooth profiles is slightly higher ($0.1\text{-}0.7\text{‰}$), especially in bovines (0.3-
 475 0.9‰), with more oscillating profiles than generally flat profiles observed in horses and red deer (Appendix
 476 D; E). Intratooth profiles ranges of $\delta^{18}\text{O}_{\text{carb}}$ are also larger within bovines ($2\text{-}4\text{‰}$) than in horses ($1\text{-}2\text{‰}$).
 477 Inverse-modelled individual $\delta^{18}\text{O}_{\text{carb}}$ ranges oscillated between $5\text{-}8\text{‰}$ and $2\text{-}4\text{‰}$, respectively. Sinusoidal
 478 curves are observed in horses and bovines, but bovine profiles are noisier. The red deer has an extensive
 479 $\delta^{18}\text{O}_{\text{carb}}$ range (6.3‰) from summer peak to an incomplete winter trough. We detect an inverse relation
 480 between $\delta^{13}\text{C}_{\text{carb}}$ and $\delta^{18}\text{O}_{\text{carb}}$ in some points of these individual profiles. MATs oscillated between 5.2°C and
 481 11.4°C (MATAs = $-5.6/+1.1\text{°C}$), with summer temperatures from 14.5°C to 27.3°C and winter temperatures
 482 from 1.9°C to -4.9°C . MAPs extend between 248mm and 521mm , notably drier than nowadays (MAPAs = -

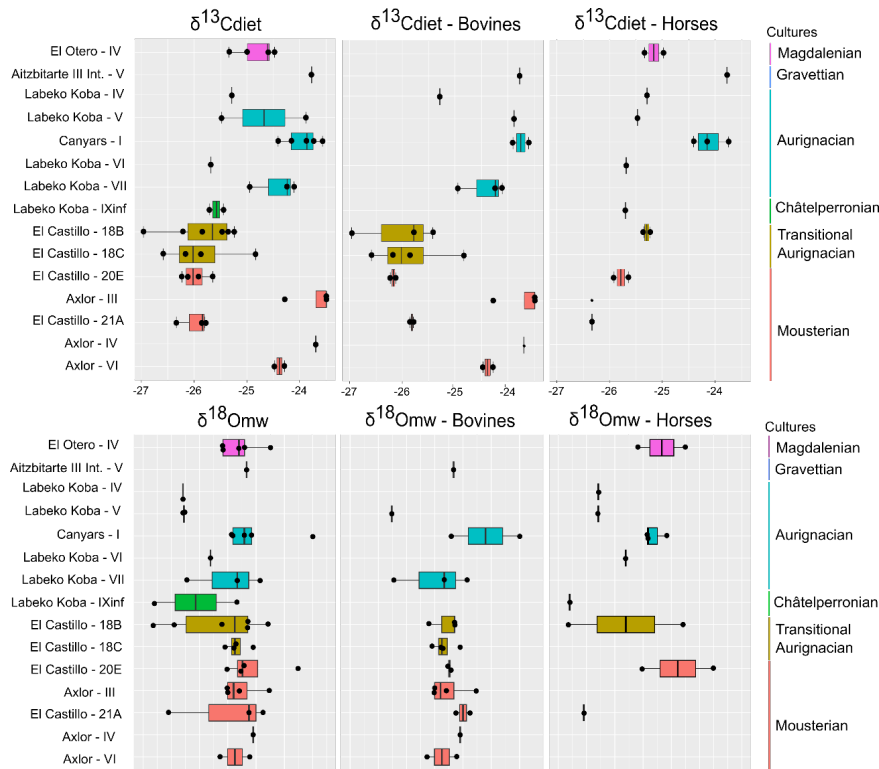

483 798/-525mm) (Table 4). Lower rainfall levels and higher seasonal amplitudes are recorded along the
484 sequence, especially in samples from the ProtoAurignacian level VII. Relevant differences are noticed
485 between MAPs estimated from bovines and equids, the first providing more arid conditions.

486 **4.4 Aitzbitarte III interior (Gravettian, 27.9 ka cal BP)**

487 A single bovine individual was analysed from Gravettian level V located in the inner part of the cave. It has
488 a high mean $\delta^{13}\text{C}_{\text{carb}}$ (-9.2‰) considering the observed range in bovines from the Vasco-Cantabrian region,
489 whereas the $\delta^{18}\text{O}_{\text{carb}}$ mean value (-5.5‰) is inside the common $\delta^{18}\text{O}_{\text{carb}}$ variation observed (Fig. 3). The
490 mean $\delta^{13}\text{C}_{\text{diet}}$ value of -23.8‰ is comparable with Canyars and some individuals from Axlor but different
491 from Labeko Koba and El Castillo individuals. The individual $\delta^{13}\text{C}_{\text{carb}}$ fluctuation is slight (0.3‰) (Appendix
492 D; E). These teeth show not quite sinusoidal profile shape in $\delta^{18}\text{O}_{\text{carb}}$, with an intratooth range of around
493 2.2‰. Climatic information is extracted but may be considered cautiously due to the profile shape and the
494 limited sample size. From the inverse modelled mean $\delta^{18}\text{O}_{\text{mw}}$ value (-5.4‰), we estimate a MAT of 13°C
495 (MATA = -0.4°C) with a summer temperature of 19.7°C and winter temperature of -2.9°C. The MAP
496 estimation reached 235mm (-1127mm to nowadays) (Table 4).

497 **4.5 El Otero (Magdalenian, ca. 17.3 ka cal BP)**

498 Two equids and three cervids are included from level IV from El Otero, recently redated and chronologically
499 related to the Magdalenian (Marín-Arroyo et al., 2018). The mean $\delta^{13}\text{C}_{\text{carb}}$ values are close, between -11.4‰
500 and -11.3‰ for red deer ($\delta^{13}\text{C}_{\text{diet}}$ = -24.4‰ and -24.6‰) and -11.6‰ and -11.3‰ for horse ($\delta^{13}\text{C}_{\text{diet}}$ = -25.3‰
501 and -25.3‰) (Fig. 3). These $\delta^{13}\text{C}$ values for both species are relatively high concerning other studied
502 samples, especially for cervids (around +1-2‰). Both species have higher $\delta^{18}\text{O}_{\text{carb}}$ values concerning the
503 common range of variation observed in the Vasco-Cantabria region, between -5‰ and -3.9‰ for horses
504 and between -5.1‰ and -4.4‰ for red deer. When values are transformed to $\delta^{13}\text{C}_{\text{diet}}$ and $\delta^{18}\text{O}_{\text{mw}}$, equids
505 and cervids isotopic niches are separated (Fig. 4). All individuals show low amplitude $\delta^{13}\text{C}_{\text{carb}}$ intratooth
506 profiles (<0.3‰), but especially equids with an intratooth variation around 0.1‰ (Appendix D; E). Equids
507 and cervids show $\delta^{18}\text{O}_{\text{carb}}$ sinusoidal profiles, with intratooth ranges between 1.4‰ and 2.4‰. Climatic
508 estimations are proposed only for equids, providing MATs estimations from 8.8°C to 12.6°C (MATAs = -4.9/
509 1°C) and MAP between 400mm and 456mm (MAPAs = -755/-699mm) (Table 4). A high-temperature
510 seasonality can be seen, with summer temperatures between 19.7°C and 23.8°C and winter temperatures
511 from -10.4°C to -3.1°C.

512
 513 **Figure 5.** Evolution of $\delta^{13}\text{C}$ in diet ($\delta^{13}\text{C}_{\text{diet}}$) and $\delta^{18}\text{O}$ in meteoric waters ($\delta^{18}\text{O}_{\text{mw}}$) by archaeological levels in a diachronic order.
 514 From right to left: all species, including cervids, bovines and horses. Colours correspond to different chrono-cultures.

515 **4.6 Canyars (Aurignacian, 39.7 ka cal BP)**

516 From the archaeological level I at Canyars, corresponding to the Aurignacian, this work includes bovines (n
 517 = 2) and equids (n = 3) teeth. The mean $\delta^{13}\text{C}_{\text{carb}}$ values for bovines are between -9‰ to -9.3‰ ($\delta^{13}\text{C}_{\text{diet}} = -$
 518 23.6‰ and -23.8‰), and for horses between -10‰ and -10.7‰ ($\delta^{13}\text{C}_{\text{diet}} = -23.7\text{‰}$ and -24.4‰) (Fig.3). In
 519 this site, the $\delta^{13}\text{C}_{\text{carb}}$ values for horses are notably higher than in the Vasco-Cantabrian region (around $+1-$
 520 2‰) (Table 3). Both species have relatively high $\delta^{18}\text{O}_{\text{carb}}$ values, but they fall inside the range of variation
 521 observed in the Vasco-Cantabrian region, between -5.5‰ and -3.6‰ in bovines and between -4.8‰ and $-$
 522 4.4‰ in horses. Bovine and equid isotopic niches overlap (Fig. 4), but different responses are seen in mean
 523 $\delta^{18}\text{O}_{\text{mw}}$ values between the two bovines, with one high mean value but close $\delta^{13}\text{C}_{\text{diet}}$ mean values.

524 All individuals show flat $\delta^{13}\text{C}_{\text{carb}}$ intratooth profiles ($<0.3\text{‰}$ variation). Some individuals analysed do not show
 525 $\delta^{18}\text{O}_{\text{carb}}$ sinusoidal profiles, with intratooth profiles moderately flat and ranging from 1.1‰ to 1.6‰ . We detect
 526 an inverse relation between $\delta^{13}\text{C}_{\text{carb}}$ and $\delta^{18}\text{O}_{\text{carb}}$ in some points of bovine individual isotopic profiles. MATs
 527 oscillated between 9.8°C and 11.9°C (MATAs = $-5.4\text{°C}/-3.3\text{°C}$), with summer temperatures from 16.3°C to
 528 27.5°C and winter temperatures from -0.5°C to 1.8°C (Table 4). MAPs extend between 211mm and 316mm
 529 (MAPAs = $-431/-326\text{mm}$). No substantial differences are noticed in the estimations based on bovines and
 530 equids because mean $\delta^{13}\text{C}$ diet values differed relatively little.

532

533 **Table 4.** Summary of paleoclimatic estimations, based on $\delta^{18}\text{O}$ for temperatures (Mean Annual Temperatures, MAT; summer;
534 winter) and in $\delta^{13}\text{C}$ for precipitation (Mean Annual Precipitations, MAP). Summer and winter temperature estimations were
535 obtained from teeth with clear seasonal profiles after modelling, while MAT was averaged between summer and winter before
536 modelling. In profiles with an unclear seasonal shape, MAT was deduced from the original average of all teeth points (values
537 marked in italics). Mean error associated to temperature estimations is 5.1 ± 0.6 (see details in Appendix B). Seasonality is
538 calculated as the temperature difference between summer and winter.

539 5. Discussion

540 5.1 Diet and ecological niches: carbon ratios

541 Carbon isotopic ratios are valuable indicators for discerning past animal diets, partially influenced by the
542 physiology of the animal. Considering species trends in the studied sites, bovines have generally higher
543 mean $\delta^{13}\text{C}_{\text{carb}}$ values (from -12.4‰ to -8.9‰) than horses (from -12.6‰ to -11.3‰), whereas the red deer
544 fall within the horses' range (from -13‰ to 11.3‰). In the northeastern site of Canyars, bovines also show
545 higher mean $\delta^{13}\text{C}_{\text{carb}}$ values (-9‰ to -9.3‰) compared to horses (-10.7‰ to -10‰). These differentiated
546 isotopic ranges for equids and bovines can be potentially linked to feeding behaviour. Still, these species
547 are expected to present different basal $\delta^{13}\text{C}_{\text{carb}}$ driven by their feeding behaviour and distinct physiological
548 characteristics. Bovines, being ruminants, have been suggested in previous studies to exhibit higher $\delta^{13}\text{C}_{\text{carb}}$
549 values due to increased methane production (Cerling and Harris, 1999; Tejada-Lara et al., 2018). Therefore,
550 transforming $\delta^{13}\text{C}_{\text{carb}}$ to $\delta^{13}\text{C}_{\text{diet}}$ values using species-specific equations is crucial to mitigate the species-
551 specific impact, particularly when comparing ruminants and non-ruminants. Bovines report $\delta^{13}\text{C}_{\text{diet}}$ values
552 between -27.5‰ and -23.5‰ and horses between -26‰ and -25‰ . These carbon compositions are typical
553 of animals feeding on C3 plants (commonly accepted range between -34‰ and -23‰), as can be expected

554 from high-latitude ecosystems during the Pleistocene (Bocherens, 2003; Cerling and Harris, 1999; Drucker,
555 2022).

556 Environmental factors such as light exposure, water stress, temperature fluctuations, salinity, and
557 atmospheric CO₂ changes can influence variations in δ¹³C values in a diet primarily based on C3 plants
558 (Bocherens, 2003; Kohn, 2010). Typically, δ¹³C_{diet} values below -27‰ (δ¹³C_{carb} = -13‰) are associated with
559 animals feeding on C3 vegetation found in closed forested environments, whereas δ¹³C_{diet} values between
560 -27‰ and -23‰ are linked to C3 open landscapes, which could include grasslands and steppe areas
561 (Bocherens, 2003). The relatively high δ¹³C_{diet} observed here points to animals predominantly feeding in
562 open environments. The canopy effect, characterised by a depletion in ¹³C isotopes due to dense tree cover,
563 seems unlikely among the analysed samples since none of the individuals reported δ¹³C_{diet} below the
564 standard cut-off of -27‰ (Drucker et al., 2008; Kohn, 2010; van der Merwe, 1991). Therefore, in general
565 terms, open mosaic landscapes, ranging from light forests to meadows and grasslands, can be inferred for
566 northwestern Iberia. Given the generally higher δ¹³C_{diet} values reported by bovines, it is likely that they were
567 foraging in more open environments than horses and can be considered predominantly grazers. Particularly,
568 bovines from El Castillo exhibit distinct feeding behaviour compared to other Vasco-Cantabrian sites, as
569 evidenced by their lower δ¹³C_{diet} values, indicating a potential preference for browsing and feeding in closer
570 environments, possibly in lightly forested areas. Both extinct aurochs (*Bos primigenius*) and steppe bison
571 (*Bison priscus*) are usually classified as grass-dominant mix-feeders during the Pleistocene, although it
572 should be noted that modern European bison (*Bison bonasus*) could include browsing in their diet (Rivals
573 et al., 2022). For aurochs, a browse-dominated mixed feeding behaviour is also frequently described.

574 The δ¹³C_{diet} range in equids also indicates feeding in open environments, suggesting a general mixed-
575 feeding pattern for the Vasco-Cantabrian region. However, individuals from northeastern Iberia are likely
576 grazing in more open environments, as evidenced by their notably higher δ¹³C_{diet} values compared to the
577 Vasco-Cantabrian region (+1-2‰). Evaluating if other factors contribute to lower δ¹³C_{diet} values in horses is
578 critical. In the case of equid from the Vasco-Cantabrian region, it should be considered that they have been
579 pretreated with a combination of NaClO and acetic acid, which could potentially affect the isotopic values.
580 Samples after organic removal pretreatment can potentially show either higher or lower δ¹³C values and
581 higher δ¹⁸O values based on previous experiments (Pellegrini and Snoeck, 2016; Snoeck and Pellegrini,
582 2015), with δ¹³C values generally varying below 0.3‰. Based on the observation that horses in the Vasco-
583 Cantabrian region present lower δ¹³C_{carb} values compared to bovines but similar mean δ¹⁸O_{carb} value ranges,
584 the influence of the pre-treatment on our samples is deemed to be limited.

585 Furthermore, the high variability in δ¹⁸O_{carb} values at El Castillo and Labeko Koba does not correlate with a
586 significant variation in δ¹³C_{carb} values. Based on dental wear and stable isotopes analysis, Middle and Late
587 Pleistocene horses (*Equus ferus*) were primarily grazers, although some rare cases have been reported as
588 mixed feeders or browsers, such as at Igue des Rameaux and Schöningen (Kuitens et al., 2015; Rivals et
589 al., 2009, 2015; Uzunidis, 2020). Horse populations from northern and eastern Europe were found to be
590 browsers or mixed feeders, while those from the Mediterranean region tend to be grazers (Rivals et al.,
591 2022).

592 Finally, the few cervids included in this study exhibit δ¹³C_{diet} values that frequently overlap with horses,
593 indicating a mixed feeding behaviour that varies from more closed environments in El Castillo to more open
594 habitats in El Otero. During the Pleistocene, the red deer (*Cervus elaphus*) exhibit a flexible, mixed-feeding
595 behaviour, consuming leaves, shrubs, forbs, grass, and sedges, similar to their present-day counterparts
596 (Merceron et al., 2021; Rivals et al., 2022). Today, this species inhabits diverse habitats ranging from
597 steppes to closed temperate forests.

598 5.2 Seasonality, mobility and water acquisition: oxygen ratios and intratooth profiles

599 Average values of $\delta^{18}\text{O}_{\text{carb}}$ in Vasco-Cantabrian individuals extend between -7.2‰ and -3.3‰ (Table 3).
600 Even if no clear species patterns in $\delta^{18}\text{O}_{\text{carb}}$ are observed, in general, bovines present slightly lower $\delta^{18}\text{O}_{\text{carb}}$
601 values from -7.2‰ to 4.8‰ than other species; horses have a significant variation from -6.6‰ to -3.3‰ and
602 red deer from -6.8‰ to -4.4‰ . In Canyars, both species have relatively high $\delta^{18}\text{O}_{\text{carb}}$ values that fall inside
603 the variation range observed in the Vasco-Cantabrian region, between -5.5‰ and -3.6‰ in bovines and
604 between -4.8‰ and -4.4‰ in horses. Each species shows different $\delta^{18}\text{O}_{\text{carb}}$ intratooth ranges, with bovines
605 between 1‰ and 3‰ , horses mostly around 1.5‰ , and red deer from 1‰ to 6‰ presenting the higher
606 ranges (Table 3; Appendix D). After applying inverse modelling to correct the dampening effect (Passey et
607 al., 2005b), the majority of teeth increase the $\delta^{18}\text{O}_{\text{carb}}$ intratooth range, between 3‰ and 8‰ for bovines and
608 2‰ and 7‰ for horses (Appendix E). Most bovines from Axló and Labeko Koba and horses from El Castillo
609 and El Otero exhibit well-defined sinusoidal profiles in their $\delta^{18}\text{O}_{\text{carb}}$ and large intratooth individual ranges,
610 related to the predominant consumption of water sources that reflect seasonal fluctuations between summer
611 and winter. Although not all samples consistently follow this pattern, specific intratooth profiles, particularly
612 those from bovines in El Castillo and Canyars, exhibit sharp profiles with narrow ranges ($<1.5\text{‰}$). This
613 phenomenon was previously reported in the region in preliminary studies conducted at the sites of El Castillo
614 (Jones et al., 2019) and in the Magdalenian levels of El Mirón cave (Geiling, 2020).

615 Non-sinusoidal profiles observed in the data can be attributed to various factors, including sample
616 techniques and preservation issues and the inherent variability in the original isotopic signal. Factors related
617 to sampling and methods can be connected to 1) the sampling process (e.g. too deep or too distant sampling
618 grooves); 2) the imprecision of the mass spectrometer measurements; 3) uncontrolled effects of samples
619 pretreatments; 4) diagenetic alterations affecting the carbonate fraction. However, it must be noted that
620 technical reasons, whether related to sampling or pretreatment, do not appear to impact the obtained results
621 significantly. First, this study reproduces the same intratooth sampling methods that previously yielded
622 reliable results in similar research (e.g., Pederzani et al., 2023, 2021a). Second, non-significant alterations
623 in intratooth profiles of pretreated horse samples (El Castillo, Labeko Koba, Otero) are noticed in comparison
624 to untreated bovid samples (Appendix D). Some bovid samples show these non-sinusoidal profiles equally.
625 In sites where both species are analysed, no correlation is observed between $\delta^{18}\text{O}_{\text{carb}}$ and $\delta^{13}\text{C}_{\text{carb}}$. In tooth
626 enamel, diagenetic alterations are generally less pronounced than in bone due to its higher mineral content.
627 However, carbonates within tooth enamel can be more susceptible to diagenesis and recrystallisation
628 compared to the phosphate fraction, which contains a more extensive reservoir of oxygen and stronger
629 oxygen bonds (Zazzo et al., 2004; Chenery et al., 2012; Bryant et al., 1996). The carbonate content in our
630 samples, ranging from 3.9% to 8.9% , is similar to the proportion found in modern tooth enamel, suggesting
631 no immediate indication of diagenetic alteration. Diagenesis can also be evaluated by comparing the isotopic
632 values of the carbonate and phosphate fractions in a sample, as there is a predictable difference between
633 them. However, phosphate fraction measurements were still unavailable in our study, except at Axló
634 (Pederzani et al., 2023) where good preservation was attested. Additionally, in the case of diagenetic
635 alteration, we would expect specimens from the same archaeological levels to be affected similarly, which
636 is not the case.

637 Based on these arguments, it is suggested that the non-sinusoidal $\delta^{18}\text{O}_{\text{carb}}$ signal observed in some
638 individuals may not be attributed to poor preservation; instead, it likely reflects the original isotopic signature
639 from water input, which appears to be non-seasonal. Several factors can explain why some teeth do not
640 reflect an evident seasonal fluctuation, which could be related to animals' mobility, the isotopic composition
641 of the water sources, and seasonal buffering within those water sources (Pederzani and Britton, 2019). The
642 main factors considered in our study are 1) the high mobility of the animals analysed among ecosystems
643 with different isotopic baselines due to large migrations; 2) the inland-coastal or short altitudinal movements
644 through the region, which lead to the acquisition of water from sources with different isotopic signal; and 3)
645 the acquisition of water from sources with no clear seasonal signal, such as large bodies of water, rivers,

646 groundwaters, or meltwaters. At mid-latitudes, the temperature effect is currently the dominant
647 factor. However, it is crucial to note that past changes in rainfall density (as the “amount effect”; Dansgaard,
648 1964) cannot be dismissed from having a more significant role then, particularly during glacial and arid
649 periods. These effects, with their potential to mask temperature oscillations, underscore the urgency and
650 importance of our research in understanding and predicting climate patterns. Furthermore, variability
651 between species and within the same species, even within populations living in the same habitat, is also
652 possible. This can be attributed to multiple factors, from minor differences in foraging and drinking behaviour
653 to slight metabolic and physiological variations, including body size, metabolic rate, breathing rate, moisture
654 content of food, and faeces, among others (Hoppe et al., 2004; Kohn, 1996; Magozzi et al., 2019).

655 Analyses of nitrogen and sulphur stable isotopes on ungulate bone collagen from Axlor, El Castillo and
656 Labeko Koba (Jones et al., 2018, 2019; Pederzani et al., 2023) have already revealed large variation ranges
657 linked to the existence of several microenvironments just in a few kilometres within the Vasco-Cantabria
658 region. Long migrations and long hunting distances cannot solely explain these diverse values because of
659 the range of species involved and their likely small-scale movements. In our study, the minimal $\delta^{13}\text{C}_{\text{carb}}$
660 intratooth variation within individuals ($<1\text{‰}$) indicates limited seasonal changes in their feeding behaviour
661 that influenced the carbon isotopic composition (Appendix D). Therefore, considering the diverse topography
662 of the Vasco-Cantabrian, characterized by steep valleys connecting the Cantabrian Cordillera with the
663 Atlantic Ocean through rivers over short distances (30-50 km), the availability in the past of a wide range of
664 water sources in small areas seems highly likely. Certain drinking behaviours can influence $\delta^{18}\text{O}$, as animals
665 may acquire water from various sources, with small streams better reflecting seasonal isotopic oscillations
666 than large lakes or evaporating ponds (see synthesis in Pederzani and Britton, 2019). Systematic
667 consumption of highly buffered water sources can significantly attenuate the final recorded signal.
668 Furthermore, rivers in the region frequently contain meltwater from snow during the winter-spring months
669 and water springs.

670 **5.3 Regional trends and ecological niches**

671 This study provides valuable insights despite the limited sample size at each archaeological level. It
672 establishes a baseline of isotopic values for northern Iberia, allowing for the evaluation of regional trends.
673 In the northwest, in the Vasco-Cantabrian region, the $\delta^{13}\text{C}_{\text{carb}}$ values obtained oscillated between -13‰ and
674 -8.9‰ and between -7.2‰ and -3.3‰ in the case of $\delta^{18}\text{O}_{\text{carb}}$ values. These values are within the range
675 expected, considering previous regional studies in ungulates (Carvalho et al., 2022; Jones et al., 2019;
676 Lécuyer et al., 2021; Pederzani et al., 2023). Although oxygen variability trends are less precise, the main
677 factor distinguishing the observed changes over time is the variation of carbon isotopic composition among
678 species and regions. The combination of mean $\delta^{13}\text{C}_{\text{diet}}$ and $\delta^{18}\text{O}_{\text{mw}}$ values (Fig. 4; 5) accentuates disparities
679 in ecological niche overlap between horses and bovines, whereas cervids and horses frequently exhibit
680 shared ecological niches. The dissimilarities between bovines and horses could be attributed to shifts in
681 feeding behaviour, which may be accompanied by ecological and environmental changes, either
682 independently or in parallel.

683 Comparing the entire dataset and across all sites, the consistently lower $\delta^{13}\text{C}_{\text{diet}}$ values in horses compared
684 to bovids throughout time suggest both animals inhabited open landscapes, with bovines exhibiting a grazer
685 preference while horses show a mix-feeding diet. Only in the Middle-to-Upper Paleolithic transition 18B and
686 18C levels of El Castillo, an exception is observed with lower $\delta^{13}\text{C}_{\text{diet}}$ values in bovines, linked to a higher
687 browser input due to a higher habitat in closer environments, such as open forests, similar to those inhabited
688 by the horses. This generates a niche overlapping between horses and bovines, most likely reflecting stable
689 conditions that could support both species in similar ecosystems. Contrarily, in the Châtelperronian and
690 early Aurignacian levels from Labeko Koba, a clear differentiation between horses and bovines is observed,
691 mainly in $\delta^{13}\text{C}_{\text{diet}}$ values, highlighting the occupation of different parts of the landscape by both species. This

692 spatially-driven niche separation between species could result from resource competition derived from an
693 unstable climatic period, where species needed to specialise to adapt to the changing conditions. Notable
694 changes are also observed in the $\delta^{18}\text{O}_{\text{carb}}$ values from Labeko Koba compared to the older El Castillo and
695 Axlor sites, with bovines exhibiting a higher fluctuation range and the lowest values in the region. These
696 trends are consistent with values observed on bone collagen from previous studies in these sites. During
697 the Middle-to-Upper Paleolithic transition in the region, by comparing horses and red deer, a decrease in
698 mean $\delta^{13}\text{C}$ (from -21‰ to -20‰) and $\delta^{15}\text{N}$ values (from 2.5‰ to 6‰) in bone collagen was observed in
699 contrast to stable red deer mean $\delta^{13}\text{C}$ (Fernández-García et al., 2023; Jones et al., 2018, 2019). This
700 decrease was previously interpreted as niche fractionation, derived from an opening landscape, that drove
701 equids into low-quality pastures compared to cervids. Pollen evidence in the region suggests a prevalence
702 of steppe vegetation and low tree cover for the Châtelperronian and Aurignacian (Iriarte-Chiapusso, 2000).

703 In the same period, Canyars in the northeastern area, higher mean $\delta^{13}\text{C}_{\text{diet}}$ are observed in both species
704 (between -23.6‰ and -24.4‰), indicating a preference for more open landscapes by bovines and equids.
705 The indication of open areas could be linked to the arid climatic conditions associated with the Heinrich
706 **Event Stadial 4**, which coincides with the formation of the studied level. This predominance of open areas
707 coincides with the presence of typical steppe herbivore species, such as *Equus hydruntinus* and *Coelodonta*
708 *antiquitatis*, the microfauna and pollen taxa, and the data offered by the use-wear analysis on ungulate
709 remains identified at the site (Daura et al., 2013; López-García et al., 2022; Rivals et al., 2017).

710 Aridity is a plausible explanation for the higher niche partitioning observed in Labeko Koba and the higher
711 $\delta^{13}\text{C}_{\text{diet}}$ values found in Canyars for both species during the Aurignacian. The $\delta^{13}\text{C}_{\text{diet}}$ results of bovines from
712 Aitzbitarte III interior during the Gravettian are consistent with the trend observed in Labeko Koba, where
713 previous studies have already suggested this time to be notably arid and cold (Arrizabalaga et al., 2010).
714 Finally, in the Magdalenian level of El Otero, higher $\delta^{13}\text{C}_{\text{diet}}$ values resemble those observed in Canyars.
715 However, this time, carbon values are related to niche partitioning between horses and red deer. In contrast,
716 higher $\delta^{18}\text{O}_{\text{mw}}$ values might indicate warmer conditions but are still associated with open landscapes in the
717 Vasco-Cantabrian area.

718 **5.4 Late Pleistocene climatic evolution in Northern Iberia**

719 Carbon and oxygen isotopes were used to estimate quantitative parameters related to past temperatures
720 and precipitation. In the case of oxygen isotopic compositions, an evaluation of environmental water
721 composition can be addressed before approaching temperature estimations. When transformed to $\delta^{18}\text{O}_{\text{mw}}$
722 using species-adapted correlations and correcting bias in sea water $\delta^{18}\text{O}_{\text{mw}}$, the summer $\delta^{18}\text{O}_{\text{mw}}$ values
723 obtained from the modelled teeth range from -8.9‰ to -2.2‰ , while the winter values range from -17.1‰ to
724 -8.9‰ . These values can be tentatively compared with the current trends observed in $\delta^{18}\text{O}_{\text{mw}}$ range recorded
725 by the IAEA station (IAEA/ WMO, 2022) in Santander (from -3.5‰ in summer to -6.6‰ in winter) and in
726 Barcelona (from -2.2‰ in summer to -6.3‰ in winter) and the OIPC (Bowen, 2022) estimations for studied
727 locations (from -1‰ to -9‰) (Appendix B). As observed in the present, Canyars exhibit mean annual $\delta^{18}\text{O}_{\text{mw}}$
728 values around -8.2‰ , which is lower than the current $\delta^{18}\text{O}_{\text{mw}}$ estimated for this location (-5.4‰) but higher
729 than Labeko Koba mean annual $\delta^{18}\text{O}_{\text{mw}}$ (-9.5‰). This raises the question of whether the baseline $\delta^{18}\text{O}_{\text{mw}}$
730 differences between Canyars and the other sites can be attributed to Mediterranean influence rather than
731 the Atlantic, assuming equivalent air circulation patterns and moisture sources experienced in the past as
732 in the present (Araguas-Araguas and Diaz Teijeiro, 2005; García-Alix et al., 2021; Moreno et al., 2021).
733 However, it's important to note that these comparisons must be approached thoughtfully, considering that
734 moisture fluxes and precipitation trends may have varied significantly during the Pleistocene and the
735 Holocene (Dansgaard, 1964; Shackleton, 1987).

736 As indicated by the climate reconstructed here, temperatures were colder, and precipitation levels were
737 notably lower in the Late Pleistocene period in this region than they are nowadays (Table 4; Appendix B).
738 From 80 to 50 ka BP, in the Mousterian levels of Axlor, temperatures were slightly colder than today, but
739 older levels showed higher differences between summer and winter temperatures. Rainfall estimations
740 exhibit an unusual arid pattern, possibly affected by bovines predominantly feeding in open areas at that
741 time. This aligns with the impact of basal feeding behaviour on rainfall estimations, as previously advised by
742 Lécuyer et al. (2021). In this case, it is not possible to isolate the effect of diet from environmental
743 interference, but previous studies have highlighted stable climatic conditions at the site (Pederzani et al.,
744 2023). Climatic reconstruction, relying on a compilation of lake sediments from northern Iberia (Moreno et
745 al., 2012) suggests that from late MIS4 to 60 ka cal BP, cold but relatively humid conditions predominated,
746 with drier conditions emerging later. Additionally, stalagmites from the Ejulve cave in the Iberian range
747 indicate a dry climate until 65.5 ka BP, preceding HE6, followed by more humid conditions afterwards (Pérez-
748 Mejías et al., 2019).

749 During the late Middle Paleolithic and early Aurignacian occupations, the observed shift in the niche
750 configuration of species suggests potential climatic perturbations. There is a decreasing trend in
751 temperatures from the Transitional Aurignacian levels in El Castillo (18C and 18B; ca. 47-46 ka cal BP) to
752 the Châtelperronian (Xinf; 45.1 ka cal BP) and Early Aurignacian (VII-V; from 40.7 to 36.3 ka cal BP) levels
753 in Labeko Koba. Lower mean annual and winter temperatures are particularly notable at El Castillo and
754 Labeko Koba. Labeko Koba levels exhibit high seasonal amplitude, especially at level VII. Additionally, there
755 is a slight decrease in rainfall and increased fluctuations from the Transitional Aurignacian levels from El
756 Castillo (18B-18C) to the Aurignacian levels in Labeko Koba (VII-V). Previous studies in the northern Iberian
757 region underlined an environmental and ecological shift after GS13/HE5, from 48 to 44 ka cal BP, based on
758 a progressive trend to colder temperatures, aridity increase, and open environmental conditions, matching
759 with the late Neanderthal occupations, followed by a population hiatus before the arrival of Anatomically
760 Modern Humans (Fernández-García et al., 2023; Vidal-Cordasco et al., 2022). This episode coincides with
761 the maximum extent of glaciers in this region, as recorded in Lake Enol and Vega Comeya and an significant
762 decrease in plant biomass and herbivore abundance around 44 to 38 ka BP (Ballesteros et al., 2020;
763 Jiménez-Sánchez et al., 2013; Ruiz-Fernández et al., 2022). Moreover, previous isotopic analyses in the
764 region pointed to some ecological alterations considering perturbations observed in the $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ of
765 bone collagen (Jones et al., 2018, 2019). This tendency of increased aridity aligns with observations made
766 in regional lake sediments from northern Iberia between 60 and 23.5 ka cal BP, marked by abrupt climate
767 changes associated with HE (Moreno et al., 2012). Supporting this, the marine core MD04-2845 in the
768 northern margin of Iberia reveals a decline in the Atlantic forest and an expansion of steppe and cold grasses
769 from 47 to 40 ka BP (Fourcade et al., 2022).

770 When comparing the environmental reconstruction of the Aurignacian period between the Vasco-Cantabrian
771 (levels V-IV from Labeko Koba) and the northeastern region (Layer I from Canyars), which are synchronous
772 to HE4 (39 ka BP), this study reveals notably lower rainfall levels for the latter. This is due to the feeding
773 behaviour observed in animals, mainly in open areas. However, these drier conditions align with the specific
774 climatic conditions expected for this period and support previous findings revealing aridity and the
775 predominance of open landscapes (Daura et al., 2013; Rivals et al., 2017). The temperature data indicates
776 that, at Canyars, colder conditions were experienced, especially during the winter season, compared to the
777 present. However, in comparison to Labeko Koba, Canyars experienced warmer conditions. As explained
778 earlier, the Mediterranean basin had consistently higher temperatures, even during colder periods. This is
779 consistent with the persistence of Mediterranean open forests in the surroundings, as indicated by other
780 studies (López-García et al., 2013; Rivals et al., 2017). Continuous natural records are lacking in the
781 northeastern Iberian margin. However, the inland stalagmite record from Ejulve Cave (Pérez-Mejías et al.,
782 2019) and the sedimentary lacustrine sequence of Cañizar de Villarquemado (González-Sampérez et al.,

783 2020) have identified the most arid intervals during HE5 and HE4. These periods were characterized by
784 steppe vegetation expansions, followed by deciduous woodland expansion. To the south, the Padul
785 sequence agrees with cold and dry conditions alternating with forest recovery (Camuera et al., 2019), as
786 documented in the Alborean Sea (Martrat et al., 2004).

787 Finally, the sites Aitzbitarte III interior (27.9 ka cal BP) and El Otero (17.3 ka cal BP) provided valuable
788 climatic insights into the Vasco-Cantabrian region during the Upper Paleolithic, specifically during the
789 Gravettian and Magdalenian, respectively. Considering previous research in the region, the climatic trend
790 reported for the Aurignacian, characterised by colder and more arid conditions, was expected to continue or
791 even intensify during the Gravettian (Fernández-García et al., 2023; Garcia-Ibaibarriga et al., 2019b;
792 Lécuyer et al., 2021). Both sites indicate lower precipitation than today in this area, indicating significant
793 aridity, with ungulates feeding predominantly in open landscapes. However, El Otero's higher mean annual
794 temperatures recorded in the Magdalenian horses respect to other sites within the Vasco-Cantabrian, are
795 consistent with a climatic amelioration following the Last Glacial Maximum (Jones et al., 2021). MIS 2 is
796 marked by the most extreme glacial conditions, as indicated by NGRIP and marine cores in Iberian margins
797 (Martrat et al., 2004; Sánchez Goñi et al., 2002). However, other regional proxies, such as lake sediment
798 and the stalagmite sequence in Pindal Cave (Moreno et al., 2010), suggest a complex and highly variable
799 climate during MIS 2. These proxies identify the coldest and most arid period within MIS 2 as the interval
800 from 18 to 14 ka cal BP rather than the global Last Glacial Maximum (23 to 19 ka cal BP).

801 5. Conclusions

802 This study provides a detailed analysis of the temporal evolution of the environment and climatic conditions
803 in northern Iberia, spanning from the Middle Paleolithic to the late Upper Paleolithic, this is from the GS21
804 to the GS2, ranging from 80 ka BP to 17 ka cal BP. In the Vasco-Cantabrian region, the results reveal a
805 heterogeneous open mosaic landscape, ranging from light forest to meadows and grasslands. This
806 landscape reconstruction is primarily inferred by the feeding locations of the studied animals and,
807 consequently, related to the ecosystems where hominins captured them. Despite shifts in niche
808 configuration observed between equids and bovines, both species typically foraging in open areas, with
809 bovines showing a higher preference for grazing. Only in El Castillo, during the late Mousterian and the
810 Transitional Aurignacian levels, bovines show unusually low $\delta^{13}\text{C}_{\text{diet}}$ related to higher browsing and
811 overlapping with horse isotopic niche. This might indicate a slightly closed mosaic landscape that could
812 sustain both species. In contrast, only horses from Canyars exhibit a preference for grazing behaviour.

813 Stable climatic conditions are described for Mousterian in Axlor and El Castillo levels from 80 to 50 ka cal
814 BP. However, some elements indicate environmental perturbations initiated during the Transitional
815 Aurignacian levels of El Castillo, around 48-45 ka BP and after HE5/GS13. After GS12 (44.2-43.3 ka BP),
816 horses and bovines are potentially occupying different ecological niches during the Châtelperronian and
817 early Aurignacian levels of Labeko Koba, pointing to a species' environmental specialisation, which can be
818 a consequence of competition for food resources during an unstable ecological period. The climatic
819 estimations indicate a temperature shift during this period, with a slight decrease in temperatures and
820 evidence of fluctuations in rainfall. Previous environmental studies on the region have underlined ecological
821 stress and increasing aridity from around 42.5 ka cal BP, which may relate to a broader ecosystem decline.
822 When comparing the environmental conditions during the Aurignacian period in the northeast (Canyars) and
823 the northwest (Labeko Koba), the first had higher baseline temperatures but also experienced higher aridity.
824 Animals continued to feed on open landscapes during the Gravettian and Magdalenian levels in the Vasco-
825 Cantabrian region, represented by Aitzbitarte III interior and El Otero. However, there is evidence of a
826 temperature recovery after the LGM at the El Otero.

827 The results presented here, derived from the first extensive sampling in the Vasco-Cantabrian, establish the
828 basis of future stable isotopic studies on faunal tooth enamel in Iberia. Despite the uncertainties inherent in
829 this work, both $\delta^{18}\text{O}$ and $\delta^{13}\text{C}$ contributed to the regional climatic characterisation, including the estimation
830 of temperatures and precipitations, as well as the seasonality range between summer and winter. The
831 potential influence of pretreatment effects and uncontrolled diagenetic alterations on the enamel carbonate
832 fraction has been assessed. However, complementary diagenetic tests, using new techniques like $\delta^{18}\text{O}_{\text{phos}}$
833 and FTIR analyses are advised in further works to gain more insights into sample preservation. Ongoing
834 sulphur, hydrogen and strontium studies will provide additional information on the mobility patterns of
835 animals hunted by Late Pleistocene hominins and, therefore, will help better understand the ecological and
836 environmental context occupied by Neanderthal and modern humans and their landscape use in this
837 particular region. Finally, a more comprehensive characterisation of the baseline oxygen values would also
838 enhance the environmental interpretation of the existing data.

839 **Appendices**

840 Appendices A, C, D and E are presented after bibliography. Raw data is presented in Appendix B, available
841 at https://github.com/ERC-Subsiliencia/Ungulate_enamel-carbonate

Field Code Changed

842 **Code availability**

843 R code used to perform plots, temperature and error calculations, Bayesian models code and inverse
844 models in this manuscript can be accessed at GitHub (https://github.com/ERC-Subsiliencia/Ungulate_enamel-carbonate).

Field Code Changed

846 **Data availability**

847 The available datasets used for this article are provided in the supplementary materials (Appendix A-E).

848 **Author contribution**

849 A.B.M.-A. got the funding and designed the research. A.B.M.-A and M.F.-G. get the permissions for sampling
850 in the regional museums. M.F.-G., K.B, and S.P. defined the analysis strategy. M.F.-G. analysed the data
851 and wrote the manuscript with critical inputs from A.B.M.-A., K.B, and S.P. J.M.G., L.A., M.F.-G., and A.C.
852 M.F.-G., L.A., J.M.G., and A.C. achieved the teeth sampling and lab sample preparation. J.D. and M.S. are
853 responsible for the excavations in Canyars and contribute to the discussion. All the authors revised and
854 commented on the manuscript.

855 **Competing interests**

856 The contact author has declared that none of the authors has any competing interests.

857 **Acknowledgements**

858 We acknowledge the Museo de Arqueología y Prehistoria de Cantabria (MUPAC), the Consejería de
859 Educación, Cultura y Deporte del Gobierno de Cantabria, the Museo de Arqueología de Bizkaia (Arkeologi
860 Museoa) and the Centro de Colecciones Patrimoniales de la Diputación Foral de Gipuzkoa (Gordailua) –
861 Provincial Government of Guipuzkoa's Heritage Collection Centre for the access to the archaeological
862 collections. We do appreciate the work achieved by H. Reade during the initial sampling, pretreatment and
863 analyses of samples undertaken at the University of Cantabria and Cambridge. We want to thank the two
864 anonymous referees for their valuable comments, which significantly improved the quality of the paper.

865 **Financial support**

866 Funding for Vasco-Cantabria research was obtained from the Spanish Ministry of Science and Innovation
867 (PID2021-125818NB-I00, HAR2017-84997-P and HAR2012-33956), the European Research Council under
868 the European Union's Horizon 2020 Research and Innovation Programme (grant agreement number
869 818299; SUBSILIENCE project) and Proyecto Puente by Consejería de Educación, Cultura y Deporte del
870 Gobierno de Cantabria. Research for Canyars was funded by the Spanish Ministry of Science and
871 Innovation (PID2020-113960GB-I00), Departament de Cultura de la Generalitat de Catalunya
872 (CLT/2022/ARQ001SOLC/128) and AGAUR (SGR2021-00337). M.F.-G. is supported by the APOSTD
873 postdoctoral fellowship (CIAPOS/2022/081/AEI/10.13039/501100011033), funded by the Generalitat
874 Valenciana and the European Social Fund. S.P. was supported by a German Academy of Sciences
875 Leopoldina postdoctoral fellowship (LPDS 2021-13) during this project. M.S. benefited from financial support
876 from a Ramon y Cajal postdoctoral grant (RYC2021-032999-I) funded by the Spanish Ministry of Science
877 and Innovation and the European Union-NextGenerationEU.

1217 **Appendix A. Sites description**

1218

1219 **A1. Vasco-Cantabrian sites**

1220 **Axlor (Dima, Vizcaya, País Vasco)**

1221 Axlor is a rock-shelter located in Dima (43.2706; -1.8905), with a continuous Middle Paleolithic sequence
1222 from the MIS5 to the MIS3 (DeMuro et al., 2023; Pederzani et al., 2023; Marín-Arroyo et al., 2018). It is
1223 placed on the southwestern slope of the Dima Valley, with an elevation of approximately 320 m above sea
1224 level (a.s.l.), at 33 km straight from the present-day coastline, next to one of the lowest mountain passes
1225 linking the Cantabrian basins and the Alavese Plateau. The site was discovered in 1932 and initial
1226 excavations were performed by Barandiarán (1967-1974). J. M. Barandiarán undertook the excavations
1227 between 1967 and 1974, identifying eight Mousterian levels (I-VIII) (Barandiarán, 1980).

1228 From 2000 to 2008, new excavations by González-Urquijo, Ibáñez-Estévez and Rios-Garaizar were
1229 achieved and, since 2019, these are ongoing by González-Urquijo and Laszúen. Due to the lack of
1230 chronology during Barandiarán excavations, among other aspects, work was focused on obtaining a detailed
1231 stratigraphy on the new excavation areas to correlate it with Barandiarán's levels (González-Urquijo &
1232 Ibáñez-Estévez, 2021; González Urquijo et al., 2005). The new stratigraphic sequence is roughly equivalent
1233 to the previous one, but with additional levels not previously identified or excavated by Barandiarán. Some
1234 of these levels were deposited before Level VIII (Gómez-Olivencia et al., 2018; 2020). The Middle Paleolithic
1235 sequence extends from layers VIII to III (or from N to B-C). Levallois production is predominant in the lower
1236 levels (VI to VIII), while Quina Mousterian technocomplex does in the upper ones (from III to V) (Rios-
1237 Garaizar, 2012, 2017). Recent chronological data by radiocarbon (Pederzani et al., 2023; Marín-Arroyo et
1238 al., 2018) and OSL (Demuro et al., 2023) methods confirm that a sequence Axlor levels VI, VIII, and VIII
1239 probably accumulated during MIS5d-a (109–82 ka), while levels D to B probably were formed during the
1240 period encompassing the start of MIS 4 (71–57 ka) through to the beginning or middle of MIS 3 (57–29 ka)
1241 and upper Level III to 46,200 ± 3,000 BP, which calibrates between 45,350 cal BP and beyond the calibration
1242 curve at > 55,000 cal BP.

1243 The archaeozoological study indicates an anthropic origin of the faunal assemblage with scarce carnivore
1244 activity documented (Altuna, 1989; Castaños, 2005; Gómez-Olivencia et al., 2018). In lower layers, the most
1245 abundant taxa are *Cervus elaphus* (VIII) and *Capra pyrenaica* (VII), while in upper layers III-V, *Cervus*
1246 *elaphus* is substituted by *Bos primigenius*/*Bison priscus* and *Equus sp.* The material included in this work
1247 comes from the faunal collection of the Barandiarán excavation currently curated at the Bizkaia Museum of
1248 Archaeology (Bilbao), where teeth were sampled, and the stable isotope analyses on enamel phosphate
1249 were included in Pederzani et al. (2023).

1250

1251 **El Castillo (Puente Viesgo, Cantabria)**

1252 El Castillo cave is located in Puente Viesgo (43.2924; -3.9656), with an elevation of approximately 195m
1253 a.s.l., at 17 km straight from the present-day coastline. The cave belongs to the karstic system that was
1254 formed in the Monte Castillo, which dominates the Pas Valley. The site was discovered in 1903 by H. Alcalde
1255 del Río. H. Obermaier carried out the first excavation seasons between 1910 and 1914 when many of the
1256 archaeological remains were recovered, mainly from the cave hall. These interventions were done under
1257 the supervision of the "Institut de Paléontologie Humaine" (IPH) and Prince Albert I of Monaco. From 1980
1258 to 2011, V. Cabrera and F. Bernaldo de Quirós underwent new excavations focusing on the cave entrance,
1259 on the Middle to Upper Paleolithic transitional levels, mainly 16, 18 and 20 (Cabrera-Valdes, 1984). The site
1260 has yielded an important stratigraphic sequence, composed by 26 sedimentological units (1-26) related to

1261 different anthropic occupational units, often separated by archaeologically sterile units: Eneolithic (2), Azilian
1262 (4), Magdalenian (6 and 8), Solutrean (10), Aurignacian (12, 14, 16 and 18), Mousterian (20, 21 and 22) and
1263 Acheulean (24) (Cabrera-Valdés, 1984).

1264 Unit 21 is mostly sterile (Cabrera Valdés, 1984; Martín-Perea et al., 2023), and ESR dated it, yielding a
1265 mean date of $69,000 \pm 9,200$ years BP (Rink et al., 1997). However, Martín-Perea et al. (2023) suggested
1266 some dating uncertainty from interpreting the initial stratigraphic nomenclature. They suggest that the ESR
1267 dates provided for level 21 by Rink et al. (1997) were erroneously attributed to this unit and it might
1268 correspond to 20E, indicating that below that subunit, the chronology is older than 70,000 years BP (Martín-
1269 Perea et al., 2023). The Mousterian Unit 20 cave is divided into several subunits (Martín-Perea et al., 2023).
1270 In Unit 20, a cave roof collapse took place, transforming the cave system into an open rock shelter. This unit
1271 contains abundant archaeological and paleontological remains. Lithic industry consists of sidescrapers,
1272 denticulates, notches and cleavers, the majority on quartzite and presents both unifacial, bifacial discoid
1273 debitage and Levallois debitage. Unit 20E was attributed to Quina Mousterian by Sánchez-Fernández and
1274 Bernaldo De Quiros (2009) and contains a Neanderthal tooth (Garralda, 2005). Considering the
1275 geochronological uncertainties for dates on 20E related to Rink et al. (1997), we have decided to rely solely
1276 on ESR date of $47,000 \pm 9400$ BP provided by Liberda et al. (2010) for this level. Unit 20C presents clear
1277 evidence of the Mousterian lithic industry and radiocarbon dates of $48,700 \pm 3,400$ uncal BP (OxA-22204)
1278 and $49,400 \pm 3,700$ uncal BP (OxA-22205) (Wood et al., 2018) and mean ESR date of $42,700 \pm 9900$ BP
1279 (Liberda et al., 2010). Level 19 is archaeologically sterile and separates Unit 20 from Unit 18 (Wood et al.,
1280 2018).

1281 Unit 18 is divided into 18A (archaeologically sterile), 18B, and 18C. Levels 18B and 18C were classified as
1282 Transitional Aurignacian, representing a gradual transformation from the Mousterian to the Aurignacian,
1283 which is unique to El Castillo cave (Cabrera et al., 2001; Maillo and Bernaldo de Quirós, 2010; Wood et al.,
1284 2018). These levels' dates and cultural attribution have been the subject of much debate (e.g. Zilhao and
1285 D'Errico, 2003; Wood et al., 2018). According to Wood et al. (2018), the last dates of these levels range
1286 between $42,000 \pm 1,500$ uncal BP (OxA-22203) and $46,000 \pm 2,400$ uncal BP (OxA-21973), which is much
1287 earlier than the start of the Aurignacian period in the Cantabrian region (Marín-Arroyo et al., 2018; Vidal-
1288 Cordasco et al., 2022). The lithic assemblage of Unit 18 appears to be dominated by Discoid/Levallois
1289 technology (Bernaldo de Quirós and Maillo-Fernández, 2009) but with a high percentage of "Upper
1290 Paleolithic" pieces. Additionally, punctual bone industry and pieces with incisions and engravings were
1291 discovered in Unit 18 (Cabrera-Valdés et al., 2001). Three deciduous tooth crowns attributed to
1292 Neanderthals were found in Unit 18B (Garralda et al., 2022). Above, Unit 17 is sterile but contains scarce
1293 lithic and faunal materials, while Level 16 was attributed to the Proto-Aurignacian, with dates of
1294 $38,600 \pm 1,000$ uncal BP (OxA-22200) (Wood et al., 2018).

1295 According to Luret et al. (2020), there was a shift in hunting practices between the Late Mousterian (unit 20)
1296 and the Transitional Aurignacian (unit 18). During the Late Mousterian, hunting strategies were less
1297 specialized, and the species hunted included red deer, horses, and bovines. However, in Unit 18, a
1298 specialization in red deer hunting is observed. However, the explanation of this shift has been proposed as
1299 a response to a cultural choice or induced by climatic changes. However, recent taphonomic studies by
1300 Sanz-Royo et al. (2023) on the old collections of Aurignacian Delta level reveal a more significant role of
1301 carnivores than shown by Luret et al. (2020). The material included in this work comes from the faunal
1302 collection recovered during the Cabrera-Valdés and Bernaldo de Quirós excavations curated at Museo de
1303 Prehistoria y Arqueología de Cantabria (MUPAC, Santander).

1304

1305 **Labeko Koba (Arrastre, Guipúzcoa, País Vasco)**

1306 Labeko Koba is a cave in the Kurtzetxiki Hill (43.0619; -2.4833), at 246 m a.s.l. and 29 km straight from the
1307 present-day Atlantic coast. In 1987 and 1988, the site was discovered due to the construction of the Arrasate
1308 ring road, and a savage excavation was carried out (Arrizabalaga, 2000a). Unfortunately, the site was
1309 destroyed after that. The stratigraphic sequence identified nine different levels. The lower Level IX was
1310 attributed to the Châtelperronian, based on the presence of three Châtelperron points. Although there is a
1311 lack of human remains in few Cantabrian Châtelperronian sites, recent research has suggested that this
1312 techno-complex was produced by Neanderthals (Maroto et al., 2012; Rios-Garaizar et al., 2022). Level VII
1313 marks the beginning of the Aurignacian sequence, likely Proto-Aurignacian, with a lithic assemblage
1314 dominated by Dufour bladelets (Arrizabalaga, 2000a). Levels VI, V, and IV contain lithic assemblages that
1315 suggested an Early Aurignacian attribution (Arrizabalaga, 2000b; Arrizabalaga et al., 2009). This site is
1316 significant because it is one of the few sites with Châtelperronian assemblages and with both Proto-
1317 Aurignacian and Early Aurignacian separated (Arrizabalaga et al., 2009).

1318 Initial radiocarbon dates were inconsistent with the stratigraphy of the site and much more recent than
1319 expected for the Early Upper Paleolithic (Arrizabalaga, 2000a). This incoherence was determined to be
1320 affected by taphonomic alterations (Wood et al., 2014). Later radiocarbon dates undertaken with an
1321 ultrafiltration pre-treatment provided a new regional framework for the regional Early Upper Paleolithic
1322 (Wood et al., 2014). The Châtelperronian layer IX inf is dated to 38,100±900 uncal BP (OxA-22562) and
1323 37,400±800 uncal BP (OxA-22560). The Proto-Aurignacian levels cover a period from 36,850±800 uncal
1324 BP (OxA-21766) to 35,250±650 uncal BP (OxA-21793). The three Early Aurignacian levels are dated to
1325 35,100±600 uncal BP (OxA-21778) for level VI, ~ 34,000 uncal BP (OxA-21767 and OxA-21779) for level
1326 V, and ~ 33,000 BP (OxA-21768 and OxA-21780) for level IV (Arrizabalaga et al., 2009).

1327 Taphonomic studies indicate an alternation in the use of the cave between carnivores and humans, the latter
1328 during short occupation periods (Villaluenda et al., 2012; Rios-Garaizar et al., 2012; Arrizabalaga et al.,
1329 2010). Labeko Koba is considered to have functioned as a natural trap where carnivores, mainly hyenas,
1330 access animal carcasses. At least in the base of Labeko Koba IX, carnivore activity was higher, and they
1331 would have consumed the same prey as humans (Villaluenga et al., 2012). The presence of humans is
1332 linked to strategic use as a campsite associated with a small assemblage of lithic artifacts. The most
1333 consumed species by Châtelperronian groups were red deer, followed by the consumption of large bovids,
1334 equids, and woolly rhinoceros. During the Aurignacian period, there was some stability in human
1335 occupations, although they still alternated with carnivore occupations (Arrizabalaga et al., 2010). Cold-
1336 adapted fauna such as reindeer and woolly rhinoceros were identified in association with the
1337 Châtelperronian. Reindeer and the woolly mammoth and arctic fox were still present during the Aurignacian
1338 levels. The original sampling of the teeth studied by this work was performed in the San Sebastian Heritage
1339 Collection headquarters, where the Guipuzcoa archaeological materials were deposited at that time.

1340

1341 **Aitzbitarte III interior (Rentería, Guipúzcoa, País Vasco)**

1342 Aitzbitarte III is an archaeological site located within the Landarbaso karstic system comprising nine caves
1343 (43.270; -1.8905). The cave is situated 220 m.a.s.l. and is 10 km away from the present-day coastline. Initial
1344 archaeological interventions were carried out at the end of the 19th century by P.M. de Soralue (Altuna,
1345 2011). Recent excavations were initially conducted in the deep zone inside the cave between 1986 and
1346 1993, where the studied tooth was recovered, and later focused on the cave entrance between 1994 and
1347 2002, by J. Altuna, K. Mariezkurrena, and J. Rios-Garaizar (Altuna et al., 2011; 2017).

1348 While the cave's entrance area contains a sequence comprising possible Mousterian and Evolved
1349 Aurignacian and Gravettian levels (Altuna et al., 2011; 2013), the stratigraphy in the inner cave presents
1350 eight levels: level VIII (some tools with Mousterian features), VII (sterile), VIb, VIa and V (Middle Gravettian

1351 technocomplex with abundance of Noailles burins), IV-II (disturbed archaeological levels) and I (surface)
1352 (Altuna et al., 2017). Levels V have dates of 24,910 uncal BP (I-15208) and 23,230 uncal BP (Ua-2243);
1353 whereas level VI extends from 23,830 ± 345 uncal BP (Ua-2628) and 25,380± 430 uncal BP (Ua-2244)
1354 (Altuna, 1992; Altuna et al., 2017), with a possible outlier dated at 21,130 uncal BP (Ua-1917).

1355 The Gravettian occupation in the inner part of the cave was initially thought to be more recent than the one
1356 in the cave entrance. However, it was not easy to correlate the two excavation areas due to different
1357 sedimentation rates. The abundant human occupations took place during a singular cold phase in the Middle
1358 Gravettian with a specialized paleoeconomy focused on the hunting of *Bos primigenius* and *Bison priscus*
1359 (85% in level VI and 68% in level V), which is unusual in the Cantabrian region mostly focused on red deer
1360 and ibex. Other ungulates present are *Cervus elaphus* and *Rupicapra rupicapra*, and to a lesser extent
1361 *Capra pyrenaica*, *Capreolus capreolus*, *Rangifer tarandus*, and *Equus ferus* (Altuna et al., 2017; Altuna &
1362 Mariezkurrena, 2020). There is a scarce representation of carnivores. The tooth studied was sampled at the
1363 Gordailua Center for Heritage Collections of the Provincial Council of Gipuzkoa.

1364

1365 **El Otero (Secadura, Voto, Cantabria)**

1366 El Otero cave is located in Secadura (Voto) (43.3565; -3.5360), at 129 m.s.a.l and 12 km from the present-
1367 day coastline, near the Matienzo valley in a coastal plain environment covered by meadows and gentle hills.
1368 The discovery was made in 1908 by Lorenzo Sierra. The site was excavated in 1963 by J. Gonzalez
1369 Echeagaray and M.A. García Guinea, in two different sectors (Sala I and Sala II) with an equivalent
1370 stratigraphic sequence (González Echeagaray, 1966). Nine levels were identified in Sala I, from level IX to
1371 level I. Levels IX and VIII were initially related to the "Aurignacian-Mousterian, based on lithics assemblages
1372 with a combination of both technocomplex features. The overlying levels VI-IV were separated by a
1373 speleothem crust (level VII) and were initially related to Aurignacian, due to the presence of end-scrapers,
1374 bone points, blades, or burins on truncation (Freeman, 1964; Rios-Garaizar, 2013). Also, perforated deer,
1375 ibex, and fox teeth were found in levels V and IV. This site lacked chronological dating methods, until a
1376 selection of material from levels VI, V and IV revealed a difference in chrono-cultural attribution (Marín-
1377 Arroyo et al., 2018). Radiocarbon results yielded younger dates for such a cultural attribution and showed
1378 significant stratigraphic inconsistency. Level VI gave a result of 12,415±55 uncal BP (OxA-32585), two dates
1379 in Level V are 12,340±55 (OxA-32509) and 10,585±50 uncal BP (OxA-32510), and a date in Level IV is
1380 15,990±80 uncal BP (OxA-32508). All these results fall into the range of the Late Upper Paleolithic
1381 (Magdalenian-Azilian initially identified in levels III-I), eliminating attribution of these levels to the Aurignacian
1382 despite the presence of apparently characteristic artefacts. Further assessments of archaeological materials
1383 will be needed.

1384 Red deer dominate the assemblage, except for level IV where horses are more abundant. Wild boar, roe
1385 deer, and ibex are also present, but large bovids are relatively rare (González Echeagaray, 1966). Level IV
1386 is the richest and most anthropogenic level, with evidence of butchering in red deer (captured in winter and
1387 early summer) and chamois (in autumn). The formation of this level involved humans and carnivores, and
1388 although certain data may suggest an anthropogenic predominance, the limited sample analyzed
1389 taphonomically and the pre-selection of preserved pieces do not allow for a definitive conclusion (Yravedra
1390 & Gómez-Castanedo, 2010). The material included in this work is curated at the Museo de Prehistoria y
1391 Arqueología de Cantabria (MUPAC, Santander).

1393 **A2. Northeastern Iberia sites**

1394 **Terrasses de la Riera dels Canyars (Gavà, Barcelona, Cataluña)**

1395 Terrasses de la Riera dels Canyars (henceforth, Canyars) is an open-air site located near Gavà (Barcelona)
1396 (41.2961;1.9797), at 28 m.s.a.l and 3 km straight from the present-day coastline. The site lies on a fluvial
1397 terrace at the confluence of Riera dels Canyars, a torrential stream between Garraf Massif, Llobregat delta
1398 and Riera de Can Llong (Daura et al., 2013). Archaeo-paleontological remains were discovered during
1399 quarries activities in 2005 and was complete excavated on 2007 by the *Grup de Recerca del Quaternari*
1400 (Daura and Sanz, 2006; Daura et al., 2013). This intervention determined nine lithological units. The
1401 paleontological and archaeological remains come exclusively from one unit, the middle luthitic unit (MLU),
1402 and specifically from layer I. The MLU is composed of coarse sandy clays and gravels, filling a paleochannel
1403 network named lower detrital unit (LDU) (Daura et al., 2013). Five radiocarbon dates were obtained on
1404 charcoals from layer I, which yield statistically consistent ages from 33,800 ±350 uncal BP to 34,900 ±340
1405 uncal BP, which results in mean age of 39,710 cal BP (from 40,890 to 38,530 cal BP) (Daura et al., 2013;
1406 this work).

1407 The layer I of the site has yielded a rich faunal assemblage, consisting of over 5,000 remains. Among the
1408 herbivores, the most common species found are *Equus ferus*, *Bos primigenius*, *Equus hydruntinus*, and
1409 *Cervus elaphus* (Daura et al., 2013; Sanz-Royo et al., 2020). *Capra* sp. and *Sus scrofa* are also present,
1410 although in lower frequencies. The carnivores found at the site are also noteworthy, with *Crocuta crocuta*
1411 and *Lynx pardinus* being the most frequent. Presence of cold-adapted fauna associated to stepped
1412 environments is recorded, such as cf. *Mammuthus* sp., *Coelodonta antiquitatis*, and *Equus hydruntinus*.
1413 Small mammal analysis, pollen, and use-wear analysis have provided further evidence that a steppe-
1414 dominated landscape surrounded the Canyars site, supporting a correlation with the Heinrich [StadialEvent](#)
1415 4, in coherence with the chronology obtained for the layer (López-García et al. 2013; 2023; Rivals et al.,
1416 2017). However, the presence of woodland is also attested by forest taxa within charcoal and pollen
1417 assemblages (Daura et al., 2013).

1418 Taphonomic study is ongoing. But several evidences point that hyenas have played an important role in the
1419 accumulation of the faunal assemblage (Daura et al., 2013; Jimenez et al. 2019). However, sporadic human
1420 presence is documented by few human modifications found in faunal remains (cutmarks and fire alterations).
1421 Although the paucity of the lithic assemblage in the site, it shows a clear attribution to Upper Palaeolithic
1422 technocomplex, most likely the Early Aurignacian (Daura et al., 2013). Recently, it was documented a
1423 perforated bone fragment, which has been identified as a perforated board for leather production (Doyon et
1424 al., 2023). All teeth included in this work were sampled in *Laboratori de la Guixera* (Ajuntament de
1425 Casteldefels) where the material is stored.

Appendix D. Intratooth curve plots

Original curves derived from enamel intratooth sampling on enamel carbonate. Provided by sites. In blue, oxygen stable isotope composition ($\delta^{18}\text{O}$), and, in brown, carbon stable isotope composition ($\delta^{13}\text{C}$). In the x-axis, the distance from Enamel Root Junction (ERJ). Notice that the y-axis can experience some variations between sites.

Appendix E. Inverse Modelling: Methodological Details and Models

The intratooth $\delta^{18}\text{O}$ profiles presented in this study were obtained through the application of inverse modelling, using an adapted version of the code published in reference (Passey et al., 2005b). This modeling approach allowed for the correction of the damping effect and the reconstruction of the original $\delta^{18}\text{O}$ input time series. The model reproduces the temporal delay between $\delta^{18}\text{O}$ changes in the animal's input and their manifestation in tooth enamel, exhibiting a consistent x-direction delay in the modelled $\delta^{18}\text{O}$ curve relative to the enamel $\delta^{18}\text{O}$ input time series. The model utilizes different species-specific parameters related to enamel formation, which vary between bovines and equids. These parameters have been established based on previous studies (Bendrey et al., 2015; Zazzo et al., 2012; Passey and Cerling, 2002; Kohn, 2004; Blumenthal et al., 2014). For *Bos/Bison* sp., the initial mineral content of enamel is fixed at 25%, the enamel appositional length is set at 1.5 mm, and the maturation length is 25 mm. For *Equus* sp., the initial mineral content of enamel is fixed at 22%, the enamel appositional length is set at 6 mm, and the maturation length is 28 mm.

In addition, the model requires other variables related to sampling geometry, as well as error estimates derived from mass spectrometer measurements. The distance between samples varies for each tooth, but as a general trend, the sampling depth on the tooth enamel surface in the samples of this study represents approximately 70% of the total enamel depth. The standard deviation of the measurements obtained from the mass spectrometer was typically set at 0.12%, taking into account the uncertainty associated with the standards. Finally, the models require a damping factor that determines the cumulative damping along the isotopic profile by adjusting the measured error (E_{meas}) to the prediction error (E_{pred}). In the teeth analysed in this study, the damping factor ranged from 0.001 to 0.1.

The most likely model solutions were selected, and summer and winter values were extracted from the $\delta^{18}\text{O}$ profiles, considering the original peaks and troughs identified in the unmodelled $\delta^{18}\text{O}$ profile. This approach was adopted to prevent the introduction of artificial peaks that the model may produce, particularly in teeth without a distinct sinusoidal shape. Flat and less sinusoidal profile are less suitable for the application of the model, given its inherent assumption of an approximately sinusoidal form. Non-sinusoidal curves can lead to complex interpretations in the model outcomes. Consequently, this methodology was not applied to analysed intratooth $\delta^{13}\text{C}$ profiles, as the examined individuals did not exhibit appreciable seasonal change.

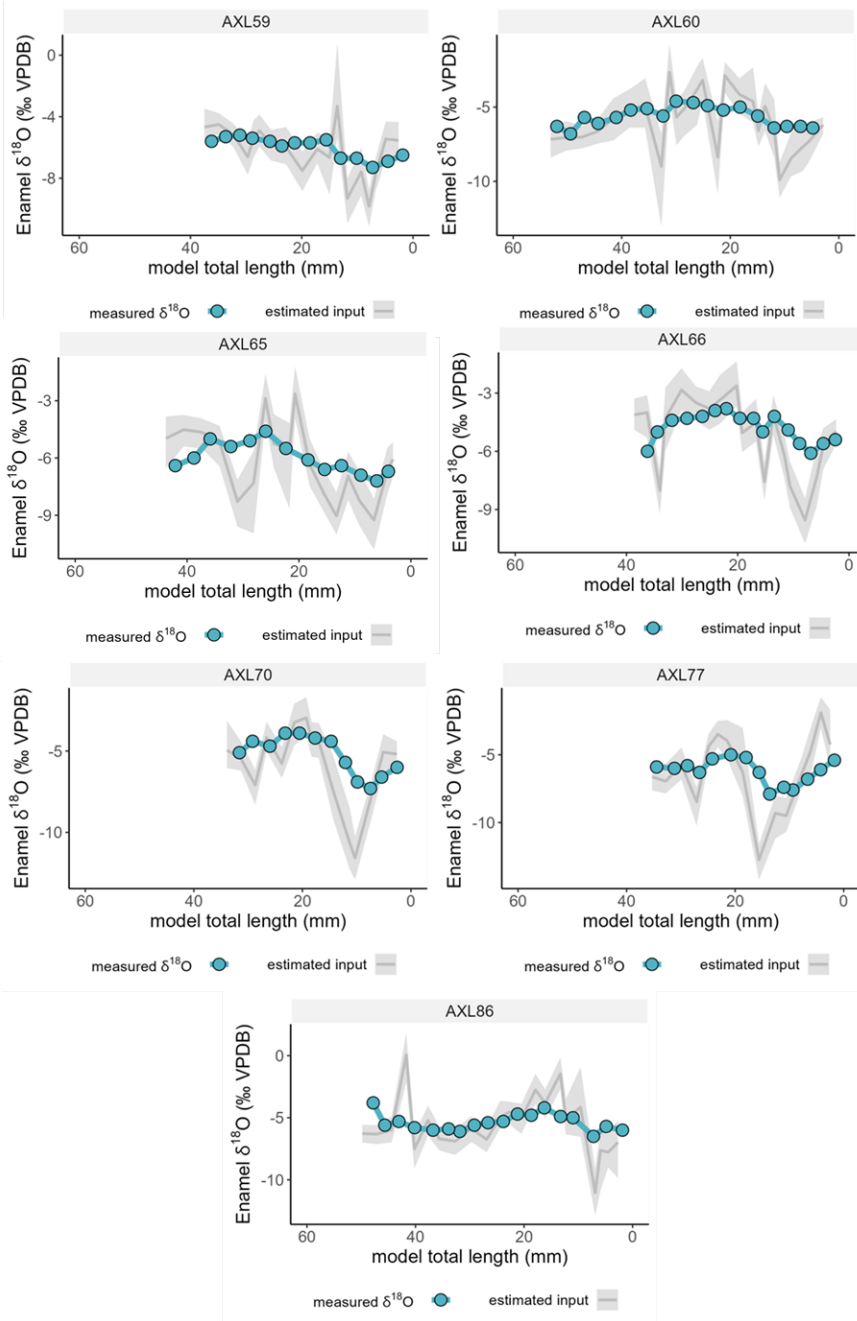

Figure E1. Inverse models for oxygen isotope composition ($\delta^{18}\text{O}$) from teeth from Axlor, considering distance from enamel root junction. The blue line and points correspond to original data and grey line the most likely model solution, with the 95% confidence interval shown in shaded areas.

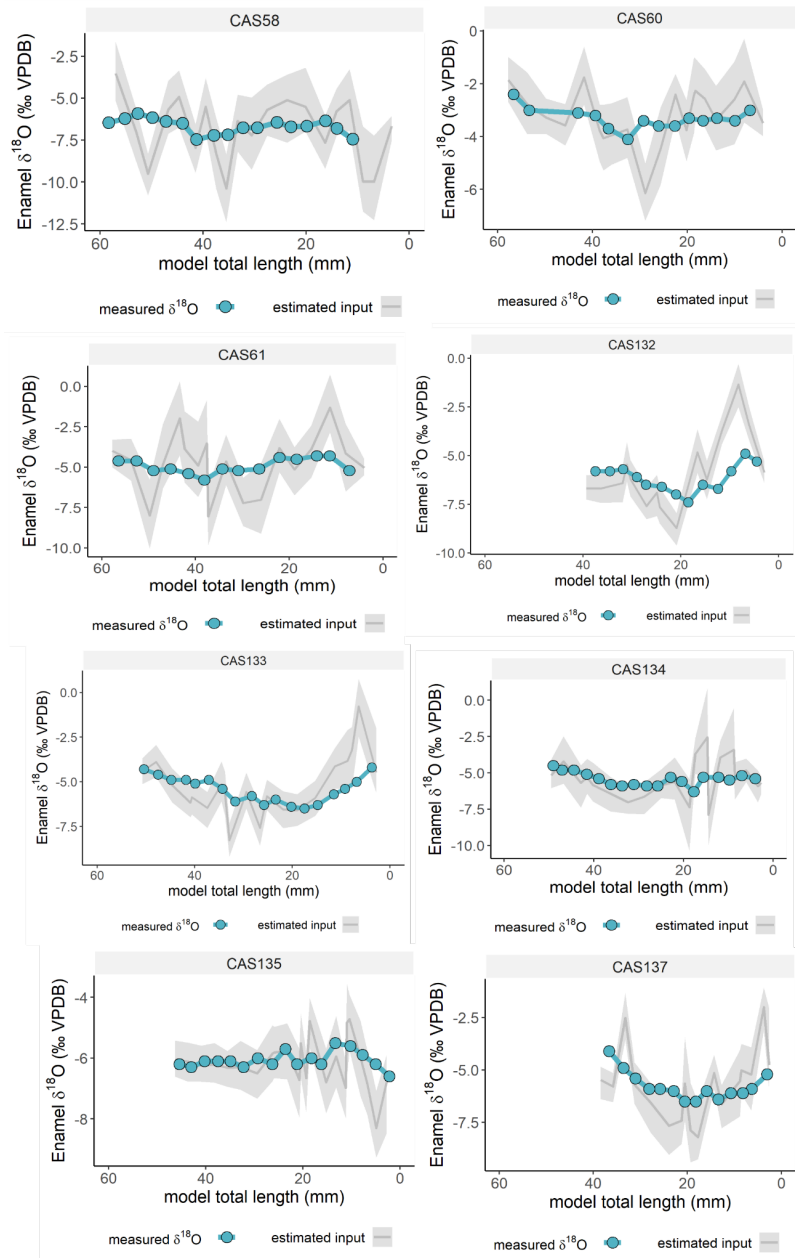

Figure E2. Inverse models for oxygen isotope composition ($\delta^{18}\text{O}$) from teeth from El Castillo, considering distance from enamel root junction. The blue line and points correspond to original data and grey line the most likely model solution, with the 95% confidence interval shown in shaded areas.

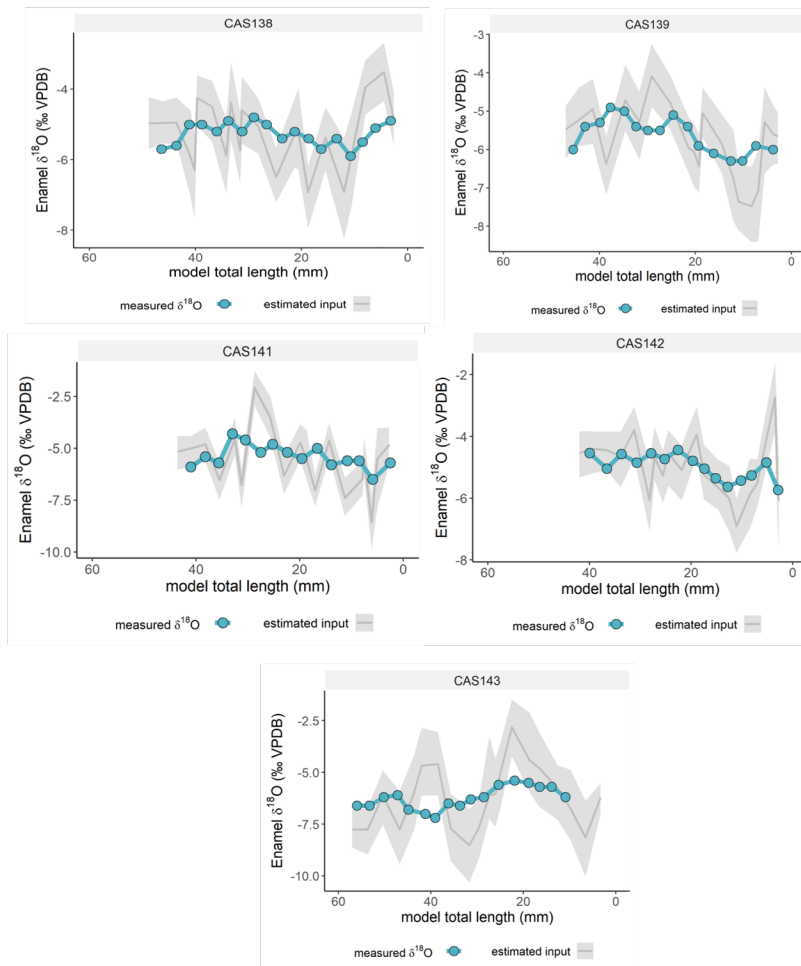

Figure E3. Inverse models for oxygen isotope composition ($\delta^{18}\text{O}$) from teeth from El Castillo, considering distance from enamel root junction. The blue line and points correspond to original data and grey line the most likely model solution, with the 95% confidence interval shown in shaded areas.

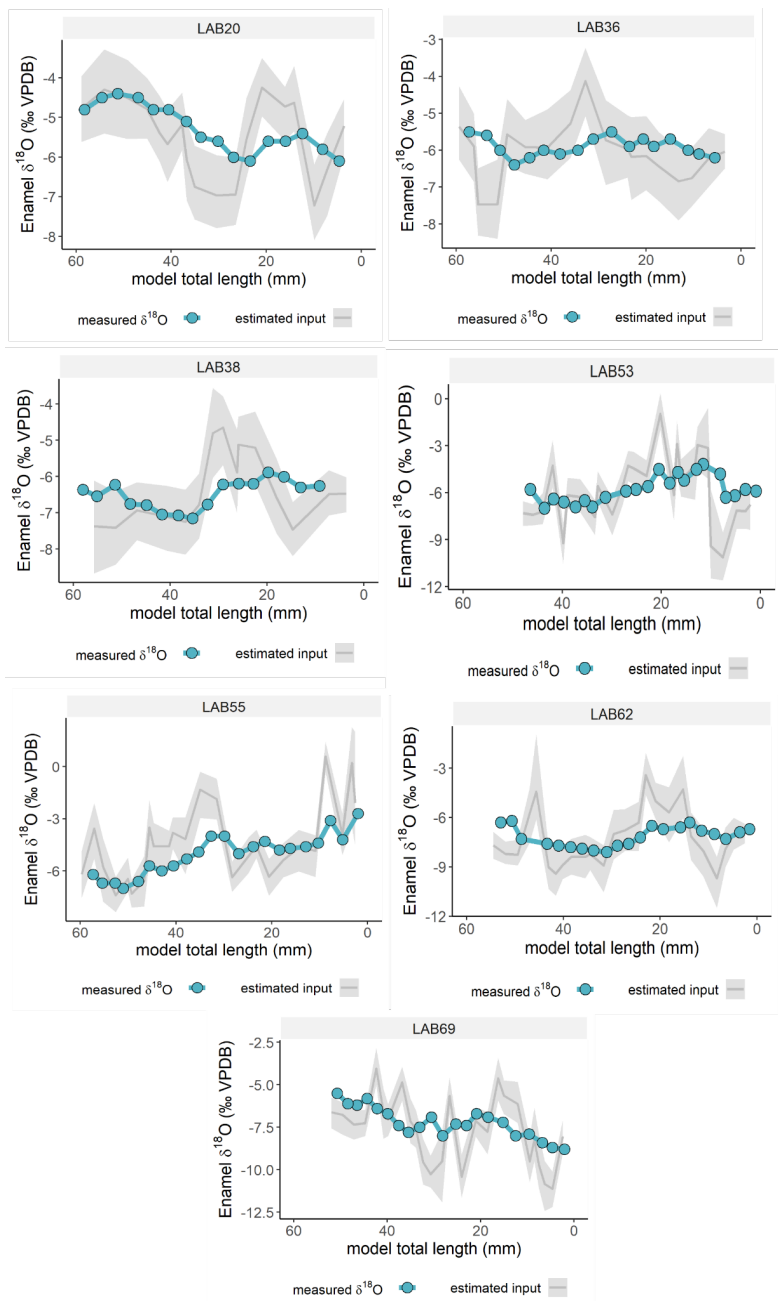

Figure E4. Inverse models for oxygen isotope composition ($\delta^{18}\text{O}$) from teeth from Labeko Koba, considering distance from enamel root junction. The blue line and points correspond to original data and grey line the most likely model solution, with the 95% confidence interval shown in shaded areas.

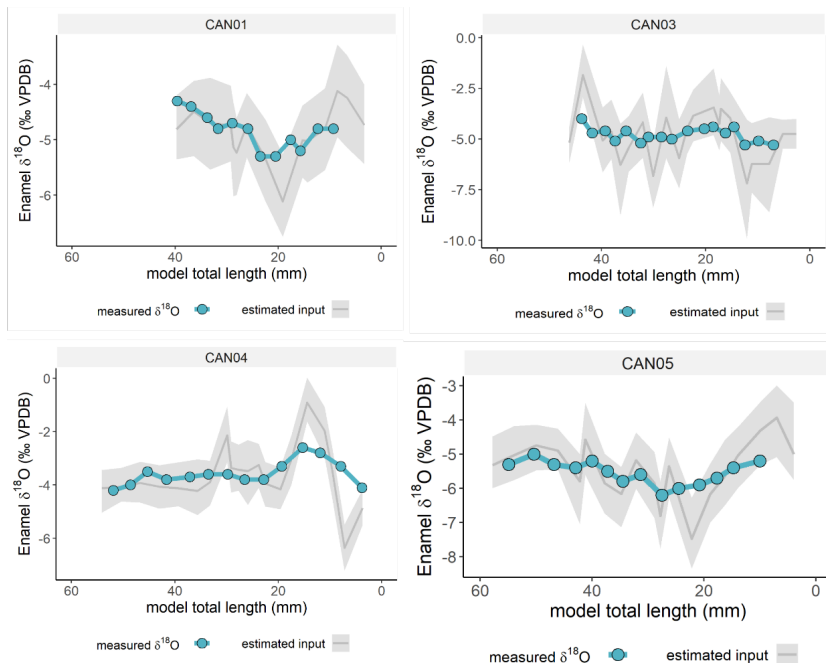

Figure E5. Inverse models for oxygen isotope composition ($\delta^{18}\text{O}$) from teeth from Canyars considering distance from enamel root junction. The blue line and points correspond to original data and grey line the most likely model solution, with the 95% confidence interval shown in shaded areas.
