14

15                  **Abstract**

16                  During the Late Pleistocene, stadial and interstadial fluctuations affected vegetation, fauna, and human  
17                  groups that were forced to cope with these pronounced climatic and environmental changes in time and  
18                  space. These changes were especially abrupt during the Marine Isotopic Stage (MIS) 3. However, little is  
19                  still known about the local and regional climatic conditions experienced by hominins in Europe. Here we  
20                  reconstruct the climatic trends in northern Iberia considering the stable isotopic composition of ungulate  
21                  skeletal tissues found in archaeological deposits dated between 80 to 15,000 cal BP. The carbon and  
22                  oxygen isotopic composition preserved in the carbonate fraction of tooth enamel provides a reliable and  
23                  high-resolution proxy of the food and water consumed by these animals, which is indirectly related to the  
24                  local vegetation, environment, and climate, allowing us to estimate paleotemperatures and rainfall data. This  
25                  study presents 44 bovine, equid, and cervid teeth from five archaeological sites in the Vasco-Cantabrian  
26                  region (El Castillo, El Otero, Axlor, Labeko Koba, Aitzbitarte III) and one in the Mediterranean area  
27                  (Canyars), where human evidence is attested from the Mousterian to the Magdalenian. The carbon isotope  
28                  values reflect animals feeding on C3 plants with a mix-feeder diet mainly developed in open environments.  
29                  However, carbon isotope value ranges point to differentiated ecological niches for equids and bovines,  
30                  especially during the Aurignacian in the Vasco-Cantabrian region. Temperature estimations based on  
31                  oxygen isotopic compositions and rainfall obtained from carbon isotopic compositions indicate colder and  
32                  more arid conditions than nowadays from the Late Mousterian to the Aurignacian. The contemporary  
33                  Mediterranean site shows slightly lower temperatures related to an arid period when animals mainly graze  
34                  in open landscapes. In the Vasco-Cantabrian region, during the MIS2, the Gravettian data reflect a  
35                  landscape opening, whereas the Magdalenian point to warmer conditions but still arid.

37                  **1. Introduction**

38                  Understanding the local and regional climatic evolution during the Late Pleistocene in southern Europe is  
39                  crucial for assessing the potential impact of climate on the adaptation and decline of Neanderthals, as well  
40                  as the subsequent expansion and resilience of Anatomically Modern Humans during the Upper Paleolithic.  
41                  During the Late Pleistocene, the climatic records demonstrate stadial and interstadial continuous  
42                  fluctuations during the Marine Isotope Stage 3 (MIS 3, ca. 60-27 ka) and MIS 2 (ca. 27-11 ka). Human  
43                  groups had to face those episodes, which affected different vegetation and fauna depending on the region.

44 Northern Iberia is a key study area due to the abundance of well-preserved archaeological caves and rock  
45 shelters where, in the last decade, an updated and multidisciplinary approach has been applied to  
46 disentangle how changing environmental conditions affected the subsistence dynamics of Middle and Upper  
47 Paleolithic hominins. Recent chronological, technological, and subsistence studies are revealing a more  
48 complex panorama than previously known.

49 The Vasco-Cantabrian region, located in northwestern Iberia, is subject to the influence of Atlantic climatic  
50 conditions and has been widely debated as a region that was significantly impacted by the glacial-interglacial  
51 oscillations during the MIS3 (Vidal-Cordasco et al., 2022). Modelling of traditional environmental proxies  
52 (small vertebrates and pollen) from archaeo-paleontological deposits show a progressive shift in the climatic  
53 conditions with decreasing temperatures and rainfall levels detected during the late Mousterian (Fernández-  
54 García et al., 2023). Ecological alterations have been observed in large mammals, such as niche partitioning  
55 between horses and cervids, a decrease in the available biomass for secondary consumers, and  
56 consequently decrease in herbivores carrying capacity (Jones et al., 2018; Vidal-Cordasco et al., 2022).  
57 Cold and arid conditions are maintained during the Aurignacian and the Gravettian until the onset of MIS2.  
58 Afterwards, during the Last Glacial Maximum (LGM, 23-19 ka), the global climatic deterioration associated  
59 with this glacial phase results in colder and more arid conditions in the region, with a predominance of open  
60 landscapes. However, this region still provided resources for human exploitation survival acting as a refugia  
61 area with more humid conditions in comparison to the Mediterranean area (Cascalheira et al., 2021; Garcia-  
62 Ibaibarriaga et al., 2019a; Lécuyer et al., 2021; Fernández-García et al., 2023; Fagoaga, 2014; Posth et al.,  
63 2023). By the end of the LGM, a climate amelioration and a moderate expansion of the deciduous forest are  
64 documented from the late Solutrean through the Magdalenian (Jones et al., 2021; Garcia-Ibaibarriaga et al.,  
65 2019a).

66 In contrast, northeastern Iberia is influenced by the Mediterranean climate. During MIS 3, this period has  
67 frequently been described as characterised by colder temperatures, higher rainfall compared to the present,  
68 and less pronounced climatic fluctuations when compared to the Vasco-Cantabrian region (López-García et  
69 al., 2014; Fernández-García et al., 2020; Vidal-Cordasco et al., 2022). Small-vertebrate communities and  
70 archaeobotanical evidence indicate relatively stable climatic conditions, but also the persistence of open  
71 forests during the Middle to Upper Paleolithic transition as in northwestern Iberia (Allué et al., 2018; Ochando  
72 et al., 2021). However, certain records indicate specific climatic excursions, such as increased aridity and  
73 landscape opening during Heinrich Events 4 and 5 (e.g., Álvarez-Lao et al., 2017; Daura et al., 2013; López-  
74 García et al., 2022; Ruffi et al., 2018).

75 These multi-proxy studies have significantly expanded our understanding of the environment in Iberia.  
76 However, there is still limited availability of high-resolution proxies directly linked to human activity. In this  
77 study, we propose to investigate the ecology and environmental dynamics of past ungulates during the late  
78 Middle and Upper Paleolithic by measuring the carbon and oxygen isotopic composition ( $\delta^{13}\text{C}$ ,  $\delta^{18}\text{O}$ ) of  
79 bioapatite carbonates preserved in archaeological mammal teeth. Tooth enamel forms incrementally and  
80 does not biologically remodel, in contrast to other body tissues such as bone, which implies that the isotope  
81 values measured on them reflect the animal diet and water sources consumed during its mineralisation,  
82 around one to two years of animal life in our study species. The preserved carbon and oxygen isotope  
83 composition in the carbonate fraction of tooth enamel offers a high-resolution record of the dietary choices  
84 of the plants and water animals consume, which indirectly reflects the vegetation, environmental conditions,  
85 and climate. This allows us to estimate past temperatures, rainfall, and moisture levels on a sub-annual  
86 scale, returning isotopic information of the foraging areas where animals were feeding during tooth  
87 formation.

88 By analysing the stable isotopic composition of 44 ungulate teeth obtained from 15 archaeological levels  
89 associated with human occupation, including El Castillo, El Otero, Axlor, Labeko Koba, Aitzbitarte III in  
90 northwestern Iberia, and Terrasses de la Riera dels Canyars in northeastern Iberia, this study presents novel  
91 insights into local and regional environmental and climatic trends during the Late Pleistocene (Fig.1; Fig.2;  
92 Appendix A). Specifically, it focuses on the Middle to Upper Paleolithic transition in both areas and the post-

93 LGM period in the Vasco-Cantabrian region. The main objectives of this work are: 1) to assess how regional  
 94 environmental conditions, including changes in moisture and vegetation cover, but also temperatures and  
 95 rainfall are recorded in tooth enamel stable isotopic composition; 2) to approach animal diet and their  
 96 ecological niches; 3) to obtain quantitative temperature data with available proxies; 4) to  
 97 characterise seasonal patterns of animals found in the archaeological sites by identifying winter and summer  
 98 fluctuations. The chronological resolution in the study areas for this period allows us to correlate regional  
 99 paleoenvironmental changes with global records.

101 **Figure 1.** Location of the archaeological sites included in this work. From west to east, in the autonomous community of  
 102 Cantabria, El Castillo, and El Otero; in the Basque Country, Axlór and Aitzbitarte III; in Catalonia, Canyars.

103

104

105 **Figure 2.** The temporal position of the archaeological levels included in the study is shown to the occurrence of different techno-  
 106 complexes in both northwestern and northeastern Iberia, as well as the  $\delta^{18}\text{O}$  record from the NGRIP ice core (North Greenland Ice  
 107 Core Project members, 2004; Rasmussen et al., 2014). Detailed chronological information is presented in Appendix B.

108 **2. Archaeological sites and sampled material**

109 This study selected a total of 44 ungulate teeth including 25 bovines (*Bos primigenius*, *Bison priscus*,  
 110 *Bos/Bison* sp.), 14 equids (*Equus* sp. and *Equus ferus*), and 5 cervids (*Cervus elaphus*) found in five  
 111 archaeological sites in the Vasco-Cantabrian region (El Castillo, El Otero, Axlór, Labeko Koba, Aitzbitarte

112 III) and one in the Mediterranean area (Terrasses de la Riera dels Canyars, henceforth Canyars. These  
 113 teeth were recovered from 15 archaeological levels attributed to the following technocomplexes: Mousterian  
 114 (n=14), Transitional Aurignacian (n=10), Châtelperronian (n=2), Aurignacian (n=12), Gravettian (n=1) and  
 115 Magdalenian (n=5) (Table 1 and 2; Appendix B). Archaeozoological studies of the archaeological sites are  
 116 available (synthesis in Marin-Arroyo and Sanz-Royo, 2022; Daura et al., 2013) and most prove that faunal  
 117 remains were accumulated by human acquisition during the different cultural phases. The isotopic results  
 118 of equids from El Castillo were previously published by Jones et al. (2019) in combination with the bone  
 119 collagen stable isotopes on ungulate prey capture at the site, as well as bioapatite phosphate analyses of  
 120 bovines from Axlor (Pederzani et al., 2023).

### 121 3. Methods

#### 122 3.1 Tooth sampling

123 All teeth included were sequentially sampled to reconstruct the complete  $\delta^{18}\text{O}$  and  $\delta^{13}\text{C}$  intratooth profiles  
 124 based on enamel carbonate bioapatite. Intratooth sequential sampling was applied to the second and third  
 125 molars and third and fourth premolars. Bovine and horse teeth sampled exceeded 3-4 cm of crown height  
 126 to ensure that at least a one-year isotopic record of animal life was obtained (Hoppe et al., 2004; Britton et  
 127 al., 2019). Samples were taken perpendicular to the growth axis on the tooth where the enamel was best  
 128 preserved, avoiding, whenever possible taphonomic alterations such as cracks or postdepositional  
 129 damages. Samples were performed in the labial face for the lower teeth and the lingual part for the upper  
 130 ones. The outermost enamel surface was abraded to remove the superficial enamel, calculus, cementum,  
 131 or concretions adhering to the surface to avoid contaminations. The sequential sampling consisted of  
 132 straight strips (ca. 8 x 1.5 x 1 mm) covering the width of the selected lobe, approximately every 2-3 mm,  
 133 from the crown to the Enamel-Root-Junction (ERJ). The sample depth covered around 75% of the enamel  
 134 depth, and dentine inclusion was avoided. A low-revolution variable-speed manual drill was used, equipped  
 135 with 1 mm diamond-coated drill bits of conical and cylindrical shape. About 10-15mg of enamel powder was  
 136 collected in each subsample, generating 693 subsamples for IRMS measures (see complete intratooth  
 137 profiles in Appendix C).

| Site            | Level - Cultural period  | Bovines   | Horses    | Red deer | Teeth     | Subsamples |
|-----------------|--------------------------|-----------|-----------|----------|-----------|------------|
| Axlor           | VI - Mousterian          | 2         |           |          | 2         | 32         |

#### 140 3.2 Sample treatment and stable isotope mass spectrometry

141 Several authors have debated the necessity of chemical pre-treatments to remove organic matter and  
 142 secondary carbonates from bioapatite carbonates before stable isotopic analysis. Some chemical  
 143 treatments can introduce secondary carbonates, increase carbonate content, and alter the original isotopic

144 signal (Snoeck and Pellegrini, 2015; Pellegrini and Snoeck, 2016). The "side effects" of these pre-treatments  
145 can compromise the final isotopic signal measured. For this reason, in this work, most of the samples were  
146 not pretreated, except for the equid samples from Labeko Koba and Aitzbitarte III, and the cervids and  
147 equids from El Otero that were sampled and pretreated in the context of the initial project. Pretreatment  
148 followed was established by Balasse et al. (2002), where around 7 mg of powdered enamel was prepared  
149 and pretreated with 3% of sodium hypochlorite (NaOCl) at room temperature for 24 h (0.1 ml/mg sample),  
150 and thoroughly rinsed with deionised water, before a reaction with 0.1M acetic acid for 4 h (0.1 ml/mg  
151 sample) (equivalent protocol in Jones et al., 2019). Samples were then thoroughly rinsed, frozen, and freeze-  
152 dried. NaOCl is one of the most common agents used for pretreating carbonates and works as a base that  
153 removes organic matter by oxidation. Although it is considered one of the most efficient agents for removing  
154 organic matter, it can induce the absorption of exogenous carbonates, such as atmospheric CO<sub>2</sub> and  
155 secondary carbonates (Snoeck and Pellegrini, 2015; Pellegrini and Snoeck, 2016). It is argued that using  
156 acetic acid after NaOCl pretreatment can remove exogenous carbonates absorbed during NaOCl  
157 application. However, it is unclear if all newly introduced carbonates are finally released and which effect  
158 they produce on the original isotopic composition. While variations in pretreatment methods exist among  
159 samples in this study, the lack of a universally accepted protocol necessitates careful consideration of any  
160 potential isotopic effects resulting from these differences. These samples were analysed in the Godwin  
161 Laboratory (Department of Earth Sciences, University of Cambridge). Enamel powder samples were reacted  
162 with 100% orthophosphoric acid for 2h at 70°C in individual vessels in an automated Gasbench interfaced  
163 with a Thermo Finnigan MAT253 isotope ratio mass spectrometer. Results were reported in reference to the  
164 international standard VPDB and calibrated using the NBS-19 standard (limestone,  $\delta^{13}\text{C} = +1.95\text{‰}$  and  $\delta^{18}\text{O}$   
165  $= -2.2\text{‰}$ ; Coplen, 2011) for which the precision is better than 0.08‰ for  $\delta^{13}\text{C}$  and 0.11‰ for  $\delta^{18}\text{O}$ .

166 For the non-pre-treated samples, carbon and oxygen stable isotopic ratios were measured using continuous  
167 flow-isotope ratio mass spectrometry, specifically a Europa Scientific 20-20 IRMS coupled to a  
168 chromatograph, at the Iso-Analytical laboratory in Cheshire, UK. The samples were weighed into clean  
169 exetainer tubes after being flushed with 99.995% helium. Phosphoric acid was then added to the samples,  
170 and they were allowed to react overnight to ensure the complete conversion of carbonate to CO<sub>2</sub>, following  
171 the method outlined by Coplen et al. (1983). The reference materials used for VPDB calibration and quality  
172 control of the analysis included: IA-R022 (calcium carbonate,  $\delta^{13}\text{C} = -28.63\text{‰}$ ,  $\delta^{18}\text{O} = -22.69\text{‰}$ ), NBS-18  
173 (carbonatite,  $\delta^{13}\text{C} = -5.01\text{‰}$ ,  $\delta^{18}\text{O} = -23.2\text{‰}$ ), IA-R066 (chalk,  $\delta^{13}\text{C} = +2.33\text{‰}$ ;  $\delta^{18}\text{O} = -1.52$ ). The accepted  
174 values of the in-house standards IA-R022 and IA-R066 were obtained by calibrating against IAEA  
175 international reference materials, NBS-18 and NBS-19, and NBS-18 and IAEA-CO-1 (Carrara marble,  $\delta^{13}\text{C}$   
176  $= 2.5\text{‰}$ , and  $\delta^{18}\text{O} = -2.4\text{‰}$ ), respectively. Additionally, in-house standards long-term measured were used:  
177 ILC1 (calcite,  $\delta^{13}\text{C} = 2.13$ ,  $\delta^{18}\text{O} = -3.99\text{‰}$ ), and Y-02 (calcite,  $\delta^{13}\text{C} = 1.48$ ,  $\delta^{18}\text{O} = -9.59\text{‰}$ ). The analytical  
178 precision of quality control standard replicates was better than 0.09‰ for  $\delta^{13}\text{C}$  and better than 0.12‰ for  
179  $\delta^{18}\text{O}$ .

### 180 3.3 Carbon stable isotopic compositions as environmental tracers

181 To unravel animal diet and to compare the different species, in standardised terms, it is necessary to  
182 consider the fractionation factor ( $\epsilon^*$ ) between  $\delta^{13}\text{C}$  obtained by the animal on its diet and  $\delta^{13}\text{C}$  recorded on  
183 enamel carbonates (Bocherens, 2003; Cerling and Harris, 1999). The  $\epsilon^*$  estimated for large ruminant  
184 mammals results in an offset of around 14.1‰ between diet and dental enamel, which is commonly applied  
185 generally to medium-sized herbivores. However, it is well-known that this offset varies between species,  
186 considering animals' different physiological parameters. Recently, a formal model to predict species-specific  
187 diet-consumer isotopic offsets has been proposed, which uses body mass (BM) and digestive physiology

188 as the main factors that regulating the  $\epsilon^*$  (Tejada-Lara et al., 2018). This model proposes the following  
189 prediction equations for ruminant or foregut fermenters (Equation 1: Eq. 1) and hindgut fermenters (Eq. 2):

190 (Eq. 1)  $\epsilon^* = 2.34 + 0.05 \text{ (BM)}$   $[r^2=0.78; \text{p-value}=0.008]$

191 (Eq. 2)  $\epsilon^* = 2.42 + 0.032 \text{ (BM)}$   $[r^2=0.74; \text{p-value}=0.003]$

192 In this work, we compare species with different digestive physiology, ruminants for bovines and cervids, and  
193 non-ruminants for equids. The  $\epsilon^*$  value was adjusted to each animal to avoid bias from digestive physiology  
194 when comparing these species. The following fractionation factors have been used: 14.6‰ for *Bos taurus*  
195 (Passey et al., 2005), 13.7‰ for *Equus caballus* (Cerling and Harris, 1999), and 13.2‰ for *Cervus elaphus*  
196 (Merceron et al. (2021) following (Eq. 1) for ruminants with a mean body mass of 125 kg.

197 Carbon isotopic composition in body tissues is considered a combination of diet (understood as consumed  
198 food), environment openness (and associated exposure to light), and the amount of precipitation. Having  
199 the precipitation in mind, Lécuyer et al. (2021) proposed to estimate Mean Annual Precipitations (MAP) from  
200  $\delta^{13}\text{C}$  preserved in enamel carbonates, derived from diets based on C3 plants. After transforming  $\delta^{13}\text{C}$  from  
201 enamel carbonate ( $\delta^{13}\text{C}_{\text{carb}}$ ) to  $\delta^{13}\text{C}$  of the diet ( $\delta^{13}\text{C}_{\text{diet}}$ ) using the fractionation factors established above,  
202 this work suggested transforming this value to  $\delta^{13}\text{C}$  from vegetation ( $\delta^{13}\text{C}_{\text{leaf}}$ ). The MAP estimation is based  
203 on least square regression developed by Rey et al. (2013) and based on Kohn (2010) dataset (Eq.4), which  
204 requires first to estimate the  $\delta^{13}\text{C}_{\text{leaf}}$  (Eq. 3). The  $\delta^{13}\text{C}$  values of atmospheric  $\text{CO}_2$  ( $\delta^{13}\text{C}_{\text{atm}}$ ) are fixed in -7‰  
205 (Lécuyer et al., 2021; Leuenberger et al., 1992; Schmitt et al., 2012).

206 (Eq.3)  $\delta^{13}\text{C}_{\text{leaf}} \text{ (VPDB)} = (\delta^{13}\text{C}_{\text{atm}} - \delta^{13}\text{C}_{\text{diet}}) / [1 + (\delta^{13}\text{C}_{\text{diet}} / 1000)]$

207

208 (Eq.4)  $\text{Log}_1(\text{MAP}+300) = 0.092(\pm 0.004) \times \delta^{13}\text{C}_{\text{leaf}} + 1.148(\pm 0.074)$

209

210 The Lécuyer et al. (2021) equation incorporates the consideration of the  $\text{pCO}_2$  effect on  $\delta^{13}\text{C}_{\text{leaf}}$  estimation,  
211 which is expected to result in an offset of +1‰ from current levels (considering that  $\text{pCO}_2$  was 180 ppm  
212 during the LGM, which is lower than the 300ppm experienced during the post deglacial around 15 ka). If this  
213 correction was not applied MAP results will be underestimated by -150mm.

### 214 3.4 Oxygen stable isotope compositions as environmental tracers

215 Intratooth profiles are known to provide a time-averaged signal compared to input isotopic signal during  
216 enamel formation (Passey et al., 2005). This signal attenuation is caused both by time-averaging effects  
217 incurred through the extended nature of amelogenesis and tooth formation, and through the sampling  
218 strategy. During mineralisation, the maturation zone, which is time-averaged, often affects a large portion of  
219 the crown height and might affect the temporal resolution of the input signal of the sample taken. To obtain  
220 climatically informative seasonal information on the analysed teeth, the application of the inverse modelling  
221 method proposed by Passey et al. (2005) is, therefore, required. This method allows us to computationally  
222 estimate the time-averaging effects of sampling and tooth formation to obtain more accurately the original  
223 amplitude of the isotopic input signal, thus to summer and winter extremes (Appendix D). This method  
224 considers parameters based on the amelogenesis trends of each species and sampling geometry, which  
225 are critical for a meaningful interpretation of intratooth isotope profiles. To evaluate the data's reproducibility  
226 and precision, the model also estimates the error derived from the uncertainty of the sampling and the mass  
227 spectrometer measurements. This method was initially developed for continuously growing teeth, taking into  
228 account a constant growth rate within a linear maturation model, which a progressive time-average  
229 increment as sampling advances along the teeth profile. The species studied in this research exhibit non-  
230 linear tooth enamel formation, particularly in later-forming molars (Bendrey et al., 2015; Zazzo et al., 2012;  
231 Passey and Cerling, 2002; Kohn, 2004; Blumenthal et al., 2014). Although the aforementioned model is not

232 ideal, as it does not account for non-linear enamel formation and certain growth parameters for the species  
233 included are unknown, it is the best estimation based on the current state of the field and remains widely  
234 used (Pederzani et al., 2023, 2021a, b).

235 Stable oxygen isotopes from meteoric water (mainly derived from rainfall) have a strong relationship with  
236 mean air temperatures in mid to high latitudes (Rozanski et al., 1992; Dansgaard, 1964) on a regional-to-  
237 local scale. Obligate drinkers, such as bovines and horses, acquire this water and record its isotopic  
238 composition in their teeth and bones with a fixed, but species-specific offset (Pederzani and Britton, 2019).  
239 Considering this two-step relationship, past climatic conditions can be estimated. However, most of the  
240 temperature reconstructions based on  $\delta^{18}\text{O}$  have considered the  $\delta^{18}\text{O}$  from the phosphate fraction of  
241 bioapatite enamel to build linear correlations between tooth enamel and drinking water  $\delta^{18}\text{O}$  and obtain  
242 climatic information. For this reason, the  $\delta^{18}\text{O}$  from carbonates values obtained in this work ( $\delta^{18}\text{O}_{\text{carb}}$ ) were  
243 converted into  $\delta^{18}\text{O}$  from phosphates ( $\delta^{18}\text{O}_{\text{phos}}$ ). To do so, first, to express in VSMOW notation, the  $\delta^{18}\text{O}$   
244 was corrected using the following correlation (Coplen et al., 1983; Brand et al., 2014):

$$245 \quad (\text{Eq.5}) \delta^{18}\text{O}_{\text{carb}} (\text{VSMOW}) = 1.0309 \times \delta^{18}\text{O}_{\text{carb}} (\text{VPDB}) + 30.91$$

246 Second, considering the relationship existent in tooth enamel between the carbonate and phosphate fraction  
247 (Iacumin et al., 1996; Pellegrini et al., 2011), from a compilation of the existent bibliography of modern  
248 animals measurements (Traylor and Kohn, 2017; Pellegrini et al., 2011; Bryant et al., 1996), Pederzani et  
249 al. (2023) proposed the following correlation:

$$250 \quad (\text{Eq.6}) \delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) = 0.941 \times \delta^{18}\text{O}_{\text{carb}} (\text{VSMOW}) - 7.16$$

251 Once the isotopic information is expressed in  $\delta^{18}\text{O}_{\text{phos}}$  (VSMOW), we can estimate the  $\delta^{18}\text{O}$  on meteoric  
252 waters ( $\delta^{18}\text{O}_{\text{mw}}$ ). It is known that different physiological factors will condition how oxygen isotope composition  
253 is fixed in each mammalian group. Thus, usually, the correlations are species-specific and developed  
254 considering the particular physiology of each animal group. The correlation employed by this work relies on  
255 recent data compilations (Pederzani et al., 2021b, 2023). In the case of horses (Eq. 7), it has been  
256 considered the data combination of Blumenthal et al. (2019); Chillón et al. (1994); Bryant et al., 1994;  
257 Delgado Huertas et al., 1995), whereas for bovines (Eq.8) the data from D'Angela and Longinelli (1990) and  
258 Hoppe (2006) have been put together in Eq. 4. To estimate  $\delta^{18}\text{O}_{\text{mw}}$  from red deer remains, we selected  
259 D'Angela and Longinelli (1990) correlation (Eq. 9):

$$260 \quad (\text{Eq.7}) \delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 22.14) / 0.87$$

$$261 \quad (\text{Eq.8}) \delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 22.13) / 0.85$$

$$262 \quad (\text{Eq.9}) \delta^{18}\text{O}_{\text{mw}} (\text{VSMOW}) = (\delta^{18}\text{O}_{\text{phos}} (\text{VSMOW}) - 24.39) / 0.91$$

263 Finally, the mean annual temperatures (MAT) were calculated from  $\delta^{18}\text{O}_{\text{mw}}$ , considering the linear regression  
264 model relating  $\delta^{18}\text{O}_{\text{mw}}$  and air temperatures from Iberia proposed by Fernández-García et al. (2019). This  
265 correlation is based on monthly climatic records (monthly mean  $\delta^{18}\text{O}_{\text{mw}}$  and monthly mean air temperatures)  
266 from all Iberian stations from the Global Network of Isotopes in Precipitation, operated by the International  
267 Atomic Energy Association and the World Meteorological Organization (IAEA/ WMO, 2018).

$$268 \quad (\text{Eq. 10}) \text{MAT } (^\circ\text{C}) = 2.38(\pm 0.10) \times \delta^{18}\text{O}_{\text{mw}} + 28.19(\pm 0.58)$$
$$269 \quad [r^2 = 0.65; n=304; p\text{-value} > 0.0001]$$

270 Following Pederzani et al. (2021b, 2021a), MAT was deduced from the  $\delta^{18}\text{O}$  mean value between summer  
271 and winter in each tooth before modeling to reduce associated error and maximise number of usable data  
272 records. Summer and winter estimations were extracted from the obtained  $\delta^{18}\text{O}$  values after inverse  
273 modeling application, to identify seasonal variation. Due to the uncertainties incurred from converting stable

274 isotope measurements to palaeotemperature, the final estimations in this work should be considered  
 275 exploratory and as a method of standardisation to make results comparable with different sites, data from  
 276 different species, and other non-isotopic palaeoclimatic records. In these estimations, the associated error  
 277 from converting  $\delta^{18}\text{O}_{\text{phos}}$  to MAT is enlarged by the uncertainty derived from the transformation of  $\delta^{18}\text{O}_{\text{carb}}$   
 278 (VPDB) to  $\delta^{18}\text{O}_{\text{phos}}$  (VSMOW) (see Pryor et al., 2014; Skrzypek et al., 2016 for further discussion).

### 279 3.4 Present-day isotopic and climatic data

280 Present-day climatic conditions surrounding each site have been considered, allowing an inter-site  
 281 comparison, essential for our study but also a regional to a global perspective. Considering current MATs  
 282 and MAPs, estimated climatic data is expressed in relative terms as MAT and MAP anomalies. Present-day  
 283 summer and winter temperatures were also considered. Present-day temperatures and precipitation values  
 284 were obtained from the WorldClim Dataset v2 (Fick and Hijmans, 2017) (Appendix B). This dataset includes  
 285 the average of bioclimatic variables between 1970-2000 in a set of raster files with a spatial resolution every  
 286 2.5 minutes. The exact location of the selected archeo-palaeontological sites was used, using geographical  
 287 coordinates in the projection on modern climatic maps with QGIS software.

288 Present-day  $\delta^{18}\text{O}_{\text{mw}}$  values from the analysed sites' areas were obtained using the Online Isotopes in  
 289 Precipitation Calculator (OIPC Version 3.1 (4/2017); Bowen, 2022) based on datasets collected by the  
 290 Global Network for Isotopes in Precipitation from the IAEA/WMO (Appendix B).

291

292 **Table 2.** Mean, maximum value (Max), minimum value (Min), and standard deviation (SD) of  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  values per  
 293 archaeological site and level organised by cultural periods. n= number of intratooth subsamples measured. In tooth type: position  
 294 (U, upper; L, lower); laterality (R, right; L, left); tooth (M, molar; P, premolar).

#### 295 4. Results

296 In northwestern Iberia, specifically in the Vasco-Cantabrian region, the mean  $\delta^{13}\text{C}_{\text{carb}}$  values range from -  
 297 8.9‰ to -13‰, with a mean value of -11‰ (SD = 1.2‰) (Table 2; Table 3). Considering species' different  
 298 fractionation factors, the  $\delta^{13}\text{C}_{\text{carb}}$  were transformed in  $\delta^{13}\text{C}_{\text{diet}}$ , resulting in mean values that extend from -  
 299 23.5‰ to -27‰ (Fig. 4). It must be considered that average values may reflect slightly different periods or  
 300 be affected by seasonal bias because different teeth encompass different periods, but it has been verified  
 301 in our teeth that the variations are limited when the seasonal information of the sequential sampling is  
 302 incorporated ( $\pm 0.2$ ; Appendix B). The carbon isotopic composition varies between species. The bovines  
 303 have generally higher mean  $\delta^{13}\text{C}_{\text{carb}}$  (from -8.9‰ to -12.4‰) than the horses (from -11.3‰ to -12.6‰),  
 304 whereas the red deer samples fall within the horses' range (from -11.3‰ to -13‰). Average values of  $\delta^{18}\text{O}_{\text{carb}}$   
 305 in all Vasco-Cantabrian individuals extend between -3.3‰ and -7.2‰ (mean = -5.5‰; SD = 0.8‰). When  
 306 transformed to  $\delta^{18}\text{O}$  expected from meteoric waters ( $\delta^{18}\text{O}_{\text{mw}}$ ), with species-adapted correlations, the  $\delta^{18}\text{O}_{\text{mw}}$   
 307 values range from -3.9‰ to -9.9‰. Less clear patterns in  $\delta^{18}\text{O}_{\text{carb}}$  are observed between bovines and horses,  
 308 with mean values of -5.7‰ and -5.2‰, respectively. In the Mediterranean area, the site of Canyars, both  
 309 species have relatively high  $\delta^{18}\text{O}_{\text{carb}}$  values that fall inside the range of variation observed in the Cantabria  
 310 region, between -3.6‰ and -5.5‰ in bovines and between -4.4‰ and -4.8‰ in case of horses.

312 **Table 3.** Mean  $\delta^{13}\text{C}$  from enamel carbonate ( $\delta^{13}\text{C}_{\text{carb}}$ ) and diet ( $\delta^{13}\text{C}_{\text{diet}}$ ), and  $\delta^{18}\text{O}$  from enamel carbonate ( $\delta^{18}\text{O}_{\text{carb}}$ ) and  
 313 meteoric waters ( $\delta^{18}\text{O}_{\text{mw}}$ ), by species on the Vasco-Cantabrian and Mediterranean areas. Max: maximum value; Min: minimum  
 314 value; SD: standard deviation.

#### 315 4.1 Axlor

316 A total of seven bovine teeth were included from levels III (n = 4), IV (n = 1), and VI (n = 2) of Axlor cave.  
 317 The mean  $\delta^{13}\text{C}_{\text{carb}}$  range from -8.9‰ to -9.9‰ ( $\delta^{13}\text{C}_{\text{diet}}$  = -23.5‰ to -24.5‰); whereas mean  $\delta^{18}\text{O}_{\text{carb}}$  values  
 318 are between -4.8‰ and -6.2‰ ( $\delta^{18}\text{O}_{\text{mw}}$  = -5.7‰ and -7.3‰), indicating a range of variation around 1‰ and  
 319 1.4‰, respectively (Fig. 3; 4). Considering isotopic compositions by levels, mean  $\delta^{13}\text{C}_{\text{carb}}$  decreases from  
 320 level III to level IV, whereas mean  $\delta^{18}\text{O}_{\text{carb}}$  remains stable through the sequence (Table 2; Appendix B). A  
 321 range between 0.3‰ and 0.5‰ is observed in  $\delta^{13}\text{C}_{\text{carb}}$  variation within tooth profiles. Individuals show clear  
 322  $\delta^{18}\text{O}$  sinusoidal profiles, with peaks and troughs, and intratooth ranges from 2.1‰ to 3.4‰. The  $\delta^{18}\text{O}_{\text{mw}}$  after  
 323 inverse modelling intratooth profiles range from -5‰ to -6.5‰ (Appendix C; D). Mean Annual Temperatures  
 324 (MATs), estimated from mean  $\delta^{18}\text{O}_{\text{mw}}$  values, with seasonal control, oscillated between 10.1°C and 14°C  
 325 (MATAs = +1.8/-2.1°C) (Table 4). From sinusoidal profiles, summer temperatures were extracted from  
 326 peaks, which are estimated to extend from 15.4°C to 23.7°C, and winter temperatures from troughs provided  
 327 values ranging from -7°C to 10.8°C. Mean Annual Precipitation (MAPs), extracted from  $\delta^{13}\text{C}_{\text{carb}}$ , extend

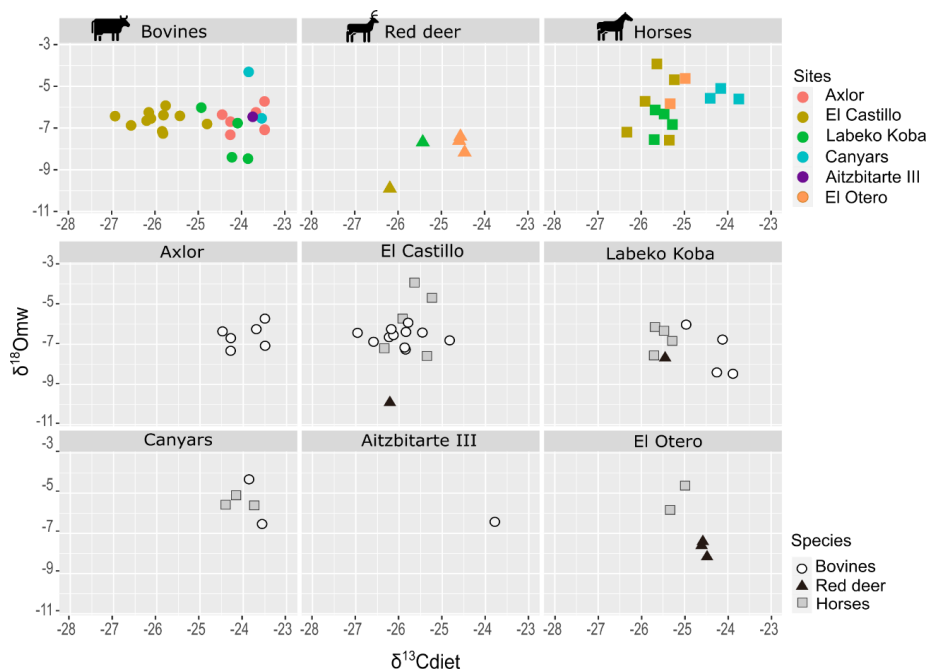

328 between 204mm and 326mm (MAPAs = -721/-843mm). Based on these estimations, a non-clear climatic  
 329 trend is observed through these levels.

330

331 **Figure 3.** Distribution of mean carbon ( $\delta^{13}\text{C}_{\text{carb}}$ ) and oxygen ( $\delta^{18}\text{O}_{\text{carb}}$ ) isotopic values from enamel carbonate for species and  
 332 archaeological site.

333  
 334

**Figure 4.** Biplot crossing  $\delta^{13}\text{C}$  from diet and  $\delta^{18}\text{O}$  from meteoric waters by species and sites.

#### 335 4.3 Labeko Koba

336 This work includes teeth of bovines ( $n = 4$ ), horses ( $n = 4$ ), and red deer ( $n = 1$ ) from levels related to  
337 Châtelperronian (IXb), ProtoAurignacian (VII), and Aurignacian (VI, V, and IV). Significant differentiation in  
338 mean  $\delta^{13}\text{C}_{\text{carb}}$  between bovines and horses is observed, with higher values between  $-9.3\text{‰}$  and  $-10.4\text{‰}$  in  
339 bovines ( $\delta^{13}\text{C}_{\text{diet}} = -23.8\text{‰}$  to  $-25\text{‰}$ ) than equids, whose values extend from  $-11.6\text{‰}$  to  $-12\text{‰}$  ( $\delta^{13}\text{C}_{\text{diet}} = -$   
340  $25.2\text{‰}$  to  $-25.8\text{‰}$ ) (Fig. 3;). These horses' values are within the ranges observed from this species in the  
341 region. Red deer have similar  $\delta^{13}\text{C}_{\text{carb}}$  values to those of horses ( $\delta^{13}\text{C}_{\text{carb}} = -12.3\text{‰}$ ;  $\delta^{13}\text{C}_{\text{diet}} = -25.5\text{‰}$ ). Mean  
342  $\delta^{18}\text{O}_{\text{carb}}$  values are similar between species from  $-4.7\text{‰}$  to  $-7.2\text{‰}$  ( $\delta^{18}\text{O}_{\text{mw}} = -6.1\text{‰}$  to  $-8.5\text{‰}$ ). However,  
343 bovines have a very high variation within mean  $\delta^{18}\text{O}$  values ( $2.1\text{‰}$ ), also reflected in the intratooth profiles.  
344 These  $\delta^{18}\text{O}$  values are lower than in other Vasco-Cantabrian sites, especially for two individuals in level VII  
345 and V (Table 3). Differences in  $\delta^{13}\text{C}$  values between bovines and horses result in isotopic niche  
346 differentiation between both species (Fig. 4). The red deer niche is placed within the horses' niche. The  
347 evolution of this niche over time cannot be evaluated by levels due to the limited sample. Considering the  
348 isotopic compositions by levels (Fig. 5), both bovines and horses experienced a slight increase in mean  $\delta^{13}\text{C}$   
349 from levels IXinf to IV, that is, from Châtelperronian to Aurignacian. Mean  $\delta^{18}\text{O}$  values of bovines decrease  
350 from VII to V, whereas in the case of horses increase from Xlinf to VI to then decrease from VI to IV.

351 Variability of  $\delta^{13}\text{C}_{\text{carb}}$  values in intratooth profiles is slightly higher ( $0.1\text{--}0.7\text{‰}$ ), especially in bovines ( $0.3\text{--}$   
352  $0.9\text{‰}$ ), with more oscillating profiles than generally flat profiles observed in horses and red deer (Appendix  
353 C; D). Intratooth profiles ranges of  $\delta^{18}\text{O}_{\text{carb}}$  are also larger within bovines ( $2\text{--}4\text{‰}$ ) than in horses ( $1\text{--}2\text{‰}$ ).  
354 Inverse modelled individual  $\delta^{18}\text{O}_{\text{carb}}$  ranges oscillated between  $5\text{--}8\text{‰}$  and  $2\text{--}4\text{‰}$ , respectively. Sinusoidal  
355 curves are observed both in horses and bovines, but bovine profiles are noisier. The red deer has a large  
356  $\delta^{18}\text{O}_{\text{carb}}$  range ( $6.3\text{‰}$ ) from summer peak to an incomplete winter thought. We detect an inverse relation  
357 between  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  in some points of these individual profiles. MATs oscillated between  $7^\circ\text{C}$  and  $13.7^\circ\text{C}$   
358 (MATAs =  $-5.6/+1.1^\circ\text{C}$ ), with summer temperatures from  $15.3^\circ\text{C}$  to  $25^\circ\text{C}$  and winter temperatures from  $0^\circ\text{C}$   
359 to  $9.1^\circ\text{C}$ . MAPs extend between  $248\text{mm}$  and  $521\text{mm}$ , which are notable drier conditions than nowadays  
360 (MAPAs =  $-798/-525\text{mm}$ ) (Table 4). Lower rainfall levels and higher seasonal amplitudes are recorded along  
361 the sequence, especially in samples from the ProtoAurignacian level VII. Relevant differences are noticed  
362 between MAPs estimated from bovines and equids, the first providing more arid conditions.

#### 363 4.4 Aitzbitarte III

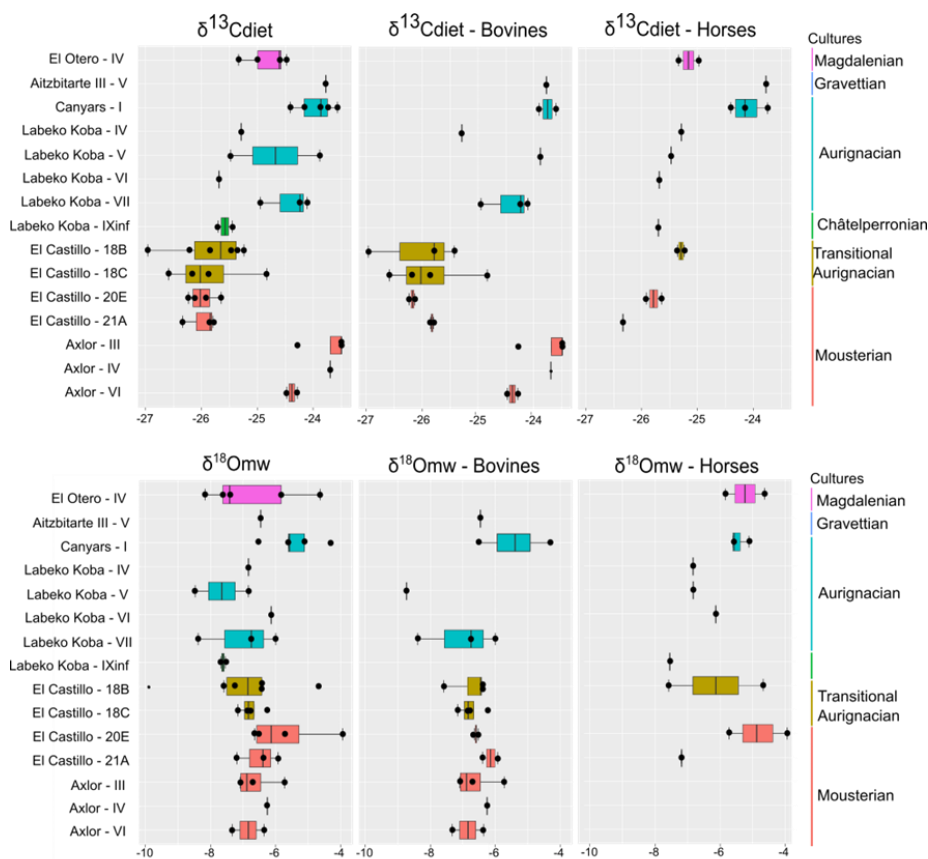

364 A single bovine individual was analysed from level V, related to Gravettian. It has a high mean  $\delta^{13}\text{C}_{\text{carb}}$  ( $-$   
365  $9.2\text{‰}$ ) considering the observed range in bovines from the Vasco-Cantabrian region, whereas the  $\delta^{18}\text{O}_{\text{carb}}$   
366 mean value ( $-5.5\text{‰}$ ) is inside the common  $\delta^{18}\text{O}$  variation observed (Fig. 3). The mean  $\delta^{13}\text{C}_{\text{diet}}$  value of  $-$   
367  $23.8\text{‰}$  is comparable with Canyars and some individuals from Axlor, but different from Labeko Koba and El  
368 Castillo individuals. The individual  $\delta^{13}\text{C}$  fluctuation is small ( $0.3\text{‰}$ ) (Appendix C; D). These teeth show not  
369 quite sinusoidal profile shape in  $\delta^{18}\text{O}_{\text{carb}}$ , with an intratooth range of around  $2.2\text{‰}$ . Climatic information is  
370 extracted but may be considered cautiously due to the profile shape and the limited sample size. From the  
371 inverse modelled mean  $\delta^{18}\text{O}_{\text{mw}}$  value ( $-5.4\text{‰}$ ), we estimate a MAT of  $14.5^\circ\text{C}$  (MATA =  $+1.1^\circ\text{C}$ ) with a summer  
372 temperature of  $17.5^\circ\text{C}$  and winter temperature of  $2.1^\circ\text{C}$ . The MAP estimation reached  $235\text{mm}$  ( $-1127\text{mm}$  to  
373 nowadays) (Table 4).

#### 374 4.5 El Otero

375 Two equids and three cervids are included from level IV from El Otero, related to the Magdalenian phase.  
376 The mean  $\delta^{13}\text{C}_{\text{carb}}$  values are close, between  $-11.3\text{‰}$  and  $-11.4\text{‰}$  for red deer ( $\delta^{13}\text{C}_{\text{diet}} = -24.4\text{‰}$  and  $-$   
377  $24.6\text{‰}$ ) and  $-11.3\text{‰}$  and  $-11.6\text{‰}$  for horse ( $\delta^{13}\text{C}_{\text{diet}} = -25\text{‰}$ ;  $-25.3\text{‰}$ ) (Fig. 3). These  $\delta^{13}\text{C}$  values for both  
378 species are relatively high concerning other studied samples, especially for cervids (around  $+1\text{--}2\text{‰}$ ). Both  
379 species have higher  $\delta^{18}\text{O}_{\text{carb}}$  values concerning the common range of variation observed in the Vasco-

380 Cantabria region, between  $-3.9\text{‰}$  and  $-5\text{‰}$  for horses and between  $-4.4\text{‰}$  and  $-5.1\text{‰}$  for red deer. When  
 381 values are transformed to  $\delta^{13}\text{C}_{\text{diet}}$  and  $\delta^{18}\text{O}_{\text{mw}}$ , equids and cervids isotopic niches are separated (Fig. 4). All  
 382 individuals show low-amplitude  $\delta^{13}\text{C}_{\text{carb}}$  intratooth profiles ( $<0.3\text{‰}$ ), but especially equids with an intratooth  
 383 variation around  $0.1\text{‰}$  (Appendix C; D). Equids and cervids show  $\delta^{18}\text{O}_{\text{carb}}$  sinusoidal profiles, with intratooth  
 384 ranges between  $1.4\text{‰}$  and  $2.4\text{‰}$ . Climatic estimations are proposed only for equids, providing MATs  
 385 estimations from  $13.4^\circ\text{C}$  to  $16.7^\circ\text{C}$  (MATAs =  $-0.3^\circ\text{C}/+3^\circ\text{C}$ ) and MAP between  $400\text{mm}$  and  $456\text{mm}$  (MAPAs  
 386 =  $-755/-699\text{mm}$ ) (Table 4). A high-temperature seasonality can be seen, with summer temperatures between  
 387  $19.4^\circ\text{C}$  and  $22.5^\circ\text{C}$  and winter temperatures from  $0.7^\circ\text{C}$  to  $7.2^\circ\text{C}$ .

388

389 **Figure 5.** Evolution of  $\delta^{13}\text{C}$  in diet ( $\delta^{13}\text{C}_{\text{diet}}$ ) and  $\delta^{18}\text{O}$  in meteoric waters ( $\delta^{18}\text{O}_{\text{mw}}$ ) by archaeological levels in a diachronic order.  
 390 From right to left: all species, including cervids, bovines and horses. Colors correspond to different chrono-cultures.

#### 391 4.6 Canyars

392 From the archaeological layer I at Canyars corresponding to the Aurignacian, this work includes bovines (n  
 393 = 2) and equids (n = 3) teeth. The mean  $\delta^{13}\text{C}_{\text{carb}}$  values for bovines are between  $-9\text{‰}$  to  $-9.3\text{‰}$  ( $\delta^{13}\text{C}_{\text{diet}} = -$   
 394  $23.6\text{‰}$  and  $-23.8\text{‰}$ ), and for horses between  $-10\text{‰}$  and  $-10.7\text{‰}$  ( $\delta^{13}\text{C}_{\text{diet}} = -23.7\text{‰}$  and  $-24.4\text{‰}$ ) (Fig.3). In  
 395 this site, the  $\delta^{13}\text{C}_{\text{carb}}$  values for horses are notably higher than samples in the Vasco-Cantabrian region  
 396 (around  $+1\text{‰}$ ) (Table 3). Both species have relatively high  $\delta^{18}\text{O}_{\text{carb}}$  values, but they fall inside the range of  
 397 variation observed in the Vasco-Cantabrian region, between  $-3.6\text{‰}$  and  $-5.5\text{‰}$  in bovines and between  $-$   
 398  $4.4\text{‰}$  and  $-4.8\text{‰}$  in horses. Different responses are seen in mean  $\delta^{18}\text{O}$  values between the two bovines,

399 with one high mean value; but with close  $\delta^{13}\text{C}$  mean values. Bovine and equid isotopic niches overlap (Fig.  
 400 4).

401 All individuals show flat  $\delta^{13}\text{C}_{\text{carb}}$  intratooth profiles (<0.3‰ variation). Some individuals analysed do not show  
 402  $\delta^{18}\text{O}$  sinusoidal profiles, with intratooth profiles moderately flat and ranging from 1.1‰ to 1.6‰. We detect  
 403 an inverse relation between  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  in some points of bovine individual isotopic profiles. MATs  
 404 oscillated between 12.5°C and 14.8°C (MATAs = -0.3°C/-2.6°C), with summer temperatures from 15.2°C to  
 405 25.2°C and winter temperatures from 7.3°C to 11.4°C (Table 4). MAPs extend between 211mm and 316mm  
 406 (MAPAs = -431/-326mm). No substantial differences are noticed in the estimations based on bovines and  
 407 equids because mean  $\delta^{13}\text{C}$  diet values differed relatively little.

| Site            | Sample | Level | Species                | MAT (°C)  |          | Summer (°C) |          | Winter (°C) |          | MAP (mm)  |          |

409 **Table 4.** Summary of paleoclimatic estimations, based on  $\delta^{18}\text{O}$  for temperatures (Mean Annual Temperatures, MAT; summer;  
 410 winter) and in  $\delta^{13}\text{C}$  for precipitation (Mean Annual Precipitations, MAP). Only teeth with validated seasonal curves are included in  
 411 the summer and winter temperature estimation after modelling teeth peaks and trough profiles. For some profiles with an unclear  
 412 seasonal shape, MATs were deduced from the original average of teeth without a seasonal profile (values marked in red). Details  
 413 on teeth selection are presented in Appendix B.

## 414 5. Discussion

### 415 5.1 Diet and ecological niches: carbon ratios

416 Carbon isotopic ratios are valuable indicators for discerning past animal diets based on the ecosystems  
 417 where the animals most frequently foraged. Considering species trends in the studied sites, bovines have  
 418 generally higher mean  $\delta^{13}\text{C}$  values (from -8.9‰ to -12.4‰) than horses (from -11.3‰ to -12.6‰), whereas  
 419 the red deer fall within the horses' range (from -11.3‰ to -13‰). In Canyars, in the Mediterranean area,

420 bovines also show higher mean  $\delta^{13}\text{C}$  values (-9‰ to -9.3‰) compared to horses (-10‰ to -10.7‰). These  
421 differentiated isotopic ranges for equids and bovines can be potentially linked to feeding behaviour, but  
422 these species are expected to present different basal  $\delta^{13}\text{C}$  considering their physiology and diet. Bovines,  
423 being ruminants, have been suggested in previous studies to exhibit higher  $\delta^{13}\text{C}$  values due to increased  
424 methane production (Cerling and Harris, 1999; Tejada-Lara et al., 2018). Therefore, transforming  $\delta^{13}\text{C}_{\text{carb}}$  to  
425  $\delta^{13}\text{C}_{\text{diet}}$  values is crucial to mitigate the species-specific impact, particularly when comparing ruminants and  
426 non-ruminants. Bovines report  $\delta^{13}\text{C}_{\text{diet}}$  values between -23.5‰ and -27.5‰ and horses between -25‰ and  
427 -26‰. These carbon compositions are typical of animals feeding on C3 plants (commonly accepted range  
428 between -34‰ and -23‰), as can be expected from high-latitude ecosystems during the Pleistocene  
429 (Cerling and Harris, 1999; Bocherens, 2003; Drucker, 2022).

430 Environmental factors such as light exposure, water stress, temperature fluctuations, salinity, and  
431 atmospheric  $\text{CO}_2$  changes can influence variations in  $\delta^{13}\text{C}$  values in a diet primarily based on C3 plants  
432 (Kohn, 2010; Bocherens, 2003). Typically,  $\delta^{13}\text{C}_{\text{diet}}$  values below -27‰ ( $\delta^{13}\text{C}_{\text{carb}} = -13‰$ ) are associated with  
433 animals feeding on C3 vegetation found in closed forested environments, whereas  $\delta^{13}\text{C}_{\text{diet}}$  values between  
434 -27‰ and -23‰ are linked to C3 open landscapes, which could include grasslands and steppe areas  
435 (Bocherens, 2003). The relatively high  $\delta^{13}\text{C}$  observed here points to animals predominantly feeding in open  
436 environments. The canopy effect, characterised by a depletion in  $^{13}\text{C}$  isotopes due to dense tree cover,  
437 seems unlikely among the analysed samples since none of the individuals reported  $\delta^{13}\text{C}_{\text{diet}}$  below the  
438 common cut-off of -27‰ (van der Merwe, 1991; Kohn, 2010; Drucker et al., 2008). Therefore, in general  
439 terms, open mosaic landscapes, ranging from light forests to meadows and grasslands, can be inferred for  
440 northwestern Iberia. Given the generally higher  $\delta^{13}\text{C}_{\text{diet}}$  values reported by bovines, it is likely that they were  
441 foraging in more open environments than horses and can be considered predominantly grazers. Particularly,  
442 bovines from El Castillo exhibit distinct feeding behavior compared to other Vasco-Cantabrian sites, as  
443 evidenced by their lower  $\delta^{13}\text{C}_{\text{diet}}$  values, indicating a potential preference for browsing and feeding in closer  
444 environments, possibly in lightly forested areas. Both extinct aurochs (*Bos primigenius*) and steppe bison  
445 (*Bison priscus*) are usually classified as grass-dominant mix-feeders during the Pleistocene, although it  
446 should be noted that modern European bison (*Bison bonasus*) could include browsing in their diet (Rivals  
447 et al., 2022). For aurochs, a browse-dominated mixed feeding behaviour is also frequently described.

448 The  $\delta^{13}\text{C}_{\text{diet}}$  range in equids indicates feeding in open environments as well, suggesting a general mix-  
449 feeding pattern for the Vasco-Cantabrian region. However, individuals from the Mediterranean area are  
450 likely grazing in more open environments, as evidenced by their notably higher  $\delta^{13}\text{C}_{\text{diet}}$  values compared to  
451 the Vasco-Cantabrian region (+1-2‰). It is important to evaluate if other factors are contributing to lower  
452  $\delta^{13}\text{C}$  values in horses. In the case of equid samples from the Vasco-Cantabrian region, it should be  
453 considered that they have been pretreated with a combination of NaClO and acetic acid, which could  
454 potentially affect the isotopic values. Samples after organic removal pretreatment can potentially show either  
455 higher or lower  $\delta^{13}\text{C}$  values and higher  $\delta^{18}\text{O}$  values based on previous experiments (Pellegrini and Snoeck,  
456 2016; Snoeck and Pellegrini, 2015), with  $\delta^{13}\text{C}$  values generally varying below 0.3‰. Based on the  
457 observation that horses in the Vasco-Cantabrian region present lower  $\delta^{13}\text{C}$  values compared to bovines but  
458 similar mean  $\delta^{18}\text{O}$  value ranges, the influence of the pre-treatment on our samples is deemed to be limited.  
459 Furthermore, the high variability in  $\delta^{18}\text{O}$  values at El Castillo and Labeko Koba does not correlate with a  
460 significant variation in  $\delta^{13}\text{C}$  values. Based on dental wear and stable isotopes analysis, Middle and Late  
461 Pleistocene horses (*Equus ferus*) were primarily grazers, although some rare cases have been reported as  
462 mixed feeders or browsers, such as at Igúe des Rameaux amont or Schöningen (Kuitens et al., 2015; Rivals  
463 et al., 2009, 2015; Uzunidis, 2020). Horse populations from northern and eastern Europe were found to be  
464 browsers or mixed feeders, while those from the Mediterranean region tend to be grazers (Rivals et al.,  
465 2022).

466 Finally, the few cervids included in this study exhibit  $\delta^{13}\text{C}_{\text{diet}}$  values that frequently overlap with those of  
467 horses, indicating a mixed feeding behaviour that varies from more closed environments in El Castillo to  
468 more open habitats in El Otero. During the Pleistocene, the red deer (*Cervus elaphus*) exhibit a flexible,  
469 mixed-feeding behavior, consuming leaves, shrubs, forbs, grass, and sedges, similar to their present-day  
470 counterparts (Rivals et al., 2022; Merceron et al., 2021). This species inhabits diverse habitats ranging from  
471 steppes to closed temperate forests.

## 472 5.2 Seasonality, mobility and water acquisition: oxygen ratios and intratooth profiles

473 Average values of  $\delta^{18}\text{O}$  in Vasco-Cantabrian individuals extend between  $-3.3\text{‰}$  and  $-7.2\text{‰}$  (Table 3). Even  
474 if no clear species patterns in  $\delta^{18}\text{O}$  are observed, in general, bovines present slightly lower  $\delta^{18}\text{O}$  values from  
475  $-4.8\text{‰}$  to  $-7.2\text{‰}$  than other species; horses have a large variation from  $-3.3\text{‰}$  to  $-6.6\text{‰}$  and red deer from  
476  $4.4\text{‰}$  to  $-6.8\text{‰}$ . In Canyars, both species have relatively high  $\delta^{18}\text{O}$  values that fall inside the variation range  
477 observed in the Vasco-Cantabrian region, between  $-3.6\text{‰}$  and  $-5.5\text{‰}$  in bovines and between  $-4.4\text{‰}$  and  
478  $4.8\text{‰}$  in horses. Each species show different  $\delta^{18}\text{O}$  intratooth ranges, with bovines between  $1\text{‰}$  and  $3\text{‰}$ ,  
479 equids mostly around  $1.5\text{‰}$ , and cervids presenting the higher ranges, from  $1\text{‰}$  to  $6\text{‰}$  (Table 3; Appendix  
480 C). After applying inverse modelling to correct the dampening effect (Passey et al., 2005), the majority of  
481 teeth increase the  $\delta^{18}\text{O}$  intratooth range, between  $3\text{‰}$  and  $8\text{‰}$  for bovines and  $2\text{‰}$  and  $7\text{‰}$  for horses  
482 (Appendix D). Most bovines from Axlor and Labeko Koba and equids from El Castillo and El Otero exhibit  
483 well-defined sinusoidal profiles in their  $\delta^{18}\text{O}$  intratooth individual values, indicating potential seasonal  
484 fluctuations between  $\delta^{18}\text{O}$  values of environmental summer and winter meteoric waters, although not all  
485 samples follow this pattern consistently. Certain intratooth profiles, particularly those from bovines in El  
486 Castillo and Canyars, exhibit sharp profiles with narrow ranges. This phenomenon was previously reported  
487 in the region in preliminary studies conducted at the sites of El Castillo (Jones et al., 2019) and in the  
488 Magdalenian levels of El Mirón cave (Geiling, 2020).

489 Non-sinusoidal profiles observed in the data can be attributed to various factors, including issues related to  
490 sample techniques and preservation and the inherent variability in the original isotopic signal. Factors related  
491 to sampling and methods can be connected to 1) the sampling process (e.g. too deep or too distant sampling  
492 grooves); 2) the imprecision of the mass spectrometer measurements; 3) uncontrolled effects of samples  
493 pretreatments; 4) diagenetic alterations affecting the carbonate fraction. However, it must be noted that  
494 technical reasons, whether related to sampling or pretreatment, do not appear to impact the obtained results  
495 significantly. First, this study reproduces the same intratooth sampling methods that previously yielded  
496 reliable results in similar research (e.g., Pederzani et al., 2023, 2021a). Second, non-significant alterations  
497 in intratooth profiles of pretreated horse samples (El Castillo, Labeko Koba, Otero) are noticed in comparison  
498 to untreated bovid samples (Appendix C). Some bovid samples are equally showing these non-sinusoidal  
499 profiles. In sites where both species are analysed, no correlation is observed between  $\delta^{18}\text{O}$  and  $\delta^{13}\text{C}$ . In  
500 tooth enamel, diagenetic alterations are generally less pronounced than bone due to its larger mineral  
501 content. However, carbonates within tooth enamel can be more susceptible to diagenesis and  
502 recrystallisation compared to the phosphate fraction, which contains a larger reservoir of oxygen and  
503 stronger oxygen bonds (Zazzo et al., 2004; Chenery et al., 2012; Bryant et al., 1996). The carbonate content  
504 in our samples, ranging from 3.9% to 8.9%, is similar to the proportion found in modern tooth enamel,  
505 suggesting no immediate indication of diagenetic alteration. Diagenesis can also be evaluated by comparing  
506 the isotopic values of the carbonate and phosphate fractions in a sample, as there is a predictable difference  
507 between them. However, phosphate fraction measurements were still unavailable in our study. Additionally,  
508 in the case of diagenetic alteration, we would expect specimens from the same archaeological levels to be  
509 affected similarly, which is not the case.

510 Based on these arguments, it is suggested that the non-sinusoidal  $\delta^{18}\text{O}$  signal observed in some individuals  
511 is likely attributed to the preservation of the original isotopic signature from water input. Several factors can

512 explain why some teeth do not reflect a clear seasonal fluctuation, which could be related to animals' mobility  
513 or the isotopic composition of the water sources. The main factors considered in our study are 1) the high  
514 mobility of the animals analysed among ecosystems with different isotopic baselines due to large migrations;  
515 2) the inland-coastal or short altitudinal movements through the region, which lead to the acquisition of water  
516 from sources with different isotopic signal; and 3) the acquisition of water from sources with no clear  
517 seasonal signal, such as large bodies of water, rivers, groundwaters, or meltwaters. Analyses of nitrogen  
518 and sulphur stable isotopes on ungulate bone collagen from Axlor, El Castillo and Labeko Koba (Jones et  
519 al., 2019, 2018; Pederzani et al., 2023) have already revealed large variation ranges linked to the existence  
520 of several microenvironments just in a few kilometres within the Vasco-Cantabria region. Long migrations  
521 and long hunting distances cannot solely explain these diversified values. In our study, the minimal  $\delta^{13}\text{C}$   
522 intratooth variation within individuals ( $<1\text{‰}$ ) indicates limited seasonal changes in their feeding behavior that  
523 influenced the carbon isotopic composition (Appendix C). Therefore, considering the Vasco-Cantabrian  
524 diverse orography with perpendicular valleys that connect the Cantabrian Cordillera with the Atlantic Ocean  
525 through rivers over short distances (30-50 km), the availability in the past of a wide range of water sources  
526 in small areas seems highly likely. Furthermore, rivers in the region frequently contain meltwater from snow  
527 during the winter-spring months, and water springs are also common.

### 528 **5.3 Regional trends and ecological niches**

529 This study provides valuable insights despite the limited sample size at each archaeological level. It  
530 establishes a baseline of isotopic values for northern Iberia, allowing for the evaluation of regional trends.  
531 In the northwest, in the Vasco-Cantabrian region, the  $\delta^{13}\text{C}_{\text{carb}}$  values obtained oscillated between  $-8.9\text{‰}$  and  
532  $-13\text{‰}$  and between  $-3.3\text{‰}$  and  $-7.2\text{‰}$  in the case of  $\delta^{18}\text{O}_{\text{carb}}$  values. These values are within the range  
533 expected, considering previous regional studies in ungulates (Lécuyer et al., 2021; Pederzani et al., 2023;  
534 Jones et al., 2019; Carvalho et al., 2022). Although oxygen variability trends are less precise, the main factor  
535 distinguishing the observed changes over time is the variation of carbon isotopic composition among species  
536 and regions. The combination of mean  $\delta^{13}\text{C}_{\text{diet}}$  and  $\delta^{18}\text{O}_{\text{mw}}$  values (Fig. 4; 5) accentuates disparities in  
537 ecological niche overlap between horses and bovines, whereas cervids and horses frequently exhibit shared  
538 ecological niches. The dissimilarities between bovines and horses could be attributed to shifts in feeding  
539 behavior, which may be accompanied by ecological and environmental changes, either independently or in  
540 parallel.

541 Upon evaluating the entire dataset by sites, the consistently lower  $\delta^{13}\text{C}$  values in horses compared to bovids  
542 throughout time suggest both animals inhabited open landscapes, with bovines exhibiting a grazer  
543 preference while horses show a mix-feeding diet. Only in the Middle-to-Upper Paleolithic transition 18B and  
544 18C levels of El Castillo, an exception is observed with lower  $\delta^{13}\text{C}$  values in bovines, linked to a higher  
545 browser input due to a higher habitat in closer environments, such as open forests, similar to those inhabited  
546 by the horses. This generates a niche overlapping between horses and bovines, most likely reflecting stable  
547 conditions that could support both species in similar ecosystems. Contrarily, in the Châtelperronian and  
548 early Aurignacian levels from Labeko Koba, a clear differentiation between horses and bovines is observed,  
549 mainly in  $\delta^{13}\text{C}$  values, highlighting the occupation of different landscapes by both species. This niche  
550 fractionation between species could result from resource competition derived from an unstable climatic  
551 period, where species needed to specialise to adapt to the changing conditions. Notable changes are also  
552 observed in the  $\delta^{18}\text{O}$  values from Labeko Koba compared to the older El Castillo and Axlor sites, with  
553 bovines exhibiting a higher fluctuation range and the lowest values in the region. These trends are consistent  
554 with values observed on bone collagen from previous studies in the studied sites. During the Middle-to-  
555 Upper Paleolithic transition in the region, by comparing horses and red deer, a decrease in mean  $\delta^{13}\text{C}$  (from  
556  $-20\text{‰}$  to  $-21\text{‰}$ ) and  $\delta^{15}\text{N}$  values (from  $6\text{‰}$  to  $2.5\text{‰}$ ) was observed in contrast to stable red deer mean  $\delta^{13}\text{C}$   
557 (Fernández-García et al., 2023; Jones et al., 2018, 2019). This decrease was already interpreted as niche

558 fractionation, derived from an opening landscape, that drove equids into low-quality pastures compared to  
559 cervids. Pollen evidence in the region suggests a prevalence of steppe vegetation and low tree cover for the  
560 Châtelperronian and Aurignacian (Iriarte-Chiapusso, 2000).

561 In the same period, at the Mediterranean site of Canyars, higher mean  $\delta^{13}\text{C}_{\text{diet}}$  are observed in both species  
562 (between  $-23.6\text{‰}$  and  $-24.4\text{‰}$ ), indicating a preference for more open landscapes by bovines and equids.  
563 The indication of open areas could be linked to the arid climatic conditions associated with the Heinrich  
564 Event 4, which coincides with the formation of the archaeological level at Canyars. This predominance of  
565 open areas coincides with the presence of typical steppe herbivore species, such as *Equus hydruntinus* and  
566 *Coelodonta antiquitatis*, the microfauna and pollen taxa, and use-wear analysis on ungulate remains  
567 identified at the site (Daura et al., 2013; López-García et al., 2022; Rivals et al., 2017). Aridity is a plausible  
568 explanation for the higher niche partitioning observed in Labeko Koba and the higher  $\delta^{13}\text{C}$  values found in  
569 Canyars for both species in Aurignacian levels. The  $\delta^{13}\text{C}_{\text{diet}}$  results of bovines from Aitzbitarte III during the  
570 Gravettian are consistent with the trend observed in Labeko Koba, and previous studies have already  
571 suggested this time to be notably arid and cold. Finally, in the Magdalenian level of El Otero, higher  $\delta^{13}\text{C}_{\text{diet}}$   
572 values resemble those observed in Canyars. However, this time, carbon values are related to niche  
573 partitioning between horses and red deer. In contrast, higher  $\delta^{18}\text{O}$  values might indicate warmer conditions  
574 but are still associated with open landscapes in the Vasco-Cantabrian area.

#### 575 **5.4 Late Pleistocene climatic evolution in Northern Iberia**

576 Carbon and oxygen isotopes were used to estimate quantitative parameters related to past temperatures  
577 and precipitation. In the case of oxygen isotopic compositions, an evaluation of environmental water  
578 composition can be addressed before approaching temperature estimations. When transformed to  $\delta^{18}\text{O}_{\text{mw}}$   
579 using species-adapted correlations, the summer  $\delta^{18}\text{O}_{\text{mw}}$  values obtained from the modelled teeth range from  
580  $-1\text{‰}$  to  $-4.9\text{‰}$ , while the winter values range from  $-4.2\text{‰}$  to  $-10.6\text{‰}$ . These values agree with the current  
581  $\delta^{18}\text{O}_{\text{mw}}$  range of values recorded by the IAEA station (IAEA/ WMO, 2022) in Santander (from  $-3.5\text{‰}$  in  
582 summer to  $-6.6\text{‰}$  in winter) and in Barcelona (from  $-2.2\text{‰}$  in summer to  $-6.3\text{‰}$  in winter) and the OIPC  
583 (Bowen, 2022) estimations for studied locations (from  $-1\text{‰}$  to  $-9\text{‰}$ ) (Appendix B). As observed in the present,  
584 Canyars exhibit higher mean annual  $\delta^{18}\text{O}_{\text{mw}}$  values of  $-5.5\text{‰}$ , which are close to the current  $\delta^{18}\text{O}_{\text{mw}}$  estimated  
585 for this location ( $-5.4\text{‰}$ ). This suggests that the baseline  $\delta^{18}\text{O}_{\text{mw}}$  differences between Canyars and the other  
586 sites can be primarily attributed to the Mediterranean influence rather than the Atlantic, assuming equivalent  
587 air circulation patterns in the past as experienced in the present and considering IAEA stations.

588 Considering this work's climatic reconstruction, temperatures are generally colder and precipitation levels  
589 are notably lower than nowadays (Table 4; Appendix B). From 80,000 to 57,000 cal BP, in the Mousterian  
590 levels of the Axlor site, temperatures are generally colder than today, but there is no clear trend observed  
591 throughout the sequence, with older levels showing higher differences between summer and winter  
592 temperatures. Rainfall estimations in these levels exhibit an unusual arid pattern, possibly affected by  
593 bovines mainly feeding in open areas. Indeed, even if the species' impact has been corrected through  
594  $\delta^{13}\text{C}_{\text{diet}}$  estimation (Tejada-Lara et al., 2018), this study observed that the influence of basal feeding  
595 behavior on rainfall estimations previously advised by Lécuyer et al. (2021) should be considered. In this  
596 case, it is not possible to isolate the effect of diet from environmental interference, but previous studies have  
597 highlighted stable climatic conditions for the site (Pederzani et al., 2023).

598 During the Middle-to-Upper Paleolithic transition and early Aurignacian occupations, a shift in the niche  
599 configuration of species is observed, indicating climatic perturbations. There is a decreasing trend in  
600 temperatures from the Transitional Aurignacian levels in El Castillo (18C and 18B; ca. 47,000 cal BP) to the  
601 Châtelperronian (Xinf; 42,100 cal BP) and Early Aurignacian (VII-V; from 41,136 to 38,570 cal BP) levels in  
602 Labeko Koba. Lower mean annual and winter temperatures are particularly notable in El Castillo, while

603 Labeko Koba exhibits high seasonal amplitude, especially in level VII. Additionally, there is a slight decrease  
604 in rainfall and increased fluctuations from the Transitional Aurignacian levels in El Castillo (18B-18C) to the  
605 Aurignacian levels in Labeko Koba (VII-V). Previous studies in the northern Iberian region underlined an  
606 environmental and ecological shift after GS13/HE5, from 48,000 to 44,000 cal BP, based on a progressive  
607 trend to colder temperatures, aridity increase, and open environmental conditions, matching with the late  
608 Neanderthal occupations, followed by a population hiatus before the arrival of Anatomically Modern Humans  
609 (Vidal-Cordasco et al., 2022; Fernández-García et al., 2023). This episode coincides with the region's  
610 maximum extension of the glaciers and a significant decrease in plant biomass and herbivore abundance  
611 (Jiménez-Sánchez et al., 2013; Ruiz-Fernández et al., 2022). Moreover, previous isotopic analyses in the  
612 region pointed to some ecological alterations considering perturbations observed in the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  of  
613 bone collagen (Jones et al., 2019, 2018).

614 When comparing the environmental reconstruction of the Aurignacian period in the Vasco-Cantabrian region  
615 (levels V-IV from Labeko Koba) and the Mediterranean region (Layer I from Canyars), which are  
616 synchronous to HE4 (39,000 BP), the study reveals notably lower rainfall levels for the Mediterranean,  
617 consistent with the feeding behavior described for animals mainly feeding in open areas. These drier  
618 conditions align with the unique climatic expectations for this period and support previous findings  
619 suggesting aridity and the predominance of open landscapes (Rivals et al., 2017; Daura et al., 2013). The  
620 temperature data indicates that Canyars experienced colder conditions, especially during the winter season,  
621 compared to the present. However, in comparison to Labeko Koba, Canyars experienced warmer  
622 conditions. As explained earlier, the Mediterranean basin had consistently higher temperatures, even during  
623 colder periods. In line with this, previous studies conducted at the site have also highlighted the persistence  
624 of Mediterranean open forests in the surroundings (Rivals et al., 2017; López-García et al., 2013).

625 Finally, the sites Aitzbitarte III (26,692 cal BP) and El Otero (19,303 cal BP) provided valuable climatic  
626 insights into the Vasco-Cantabrian region during the Upper Paleolithic, specifically during the Gravettian and  
627 Magdalenian periods, respectively. Considering previous research in the region, the climatic trend reported  
628 for the Aurignacian, characterised by colder and more arid conditions, was expected to continue or even  
629 intensify during the Gravettian period (Fernández-García et al., 2023; García-Ibaibarriaga et al., 2019b;  
630 Lécuyer et al., 2021). Both sites exhibit lower precipitation levels compared to the present, indicating  
631 significant aridity, supported by the animals predominantly feeding in open landscapes. El Otero's higher  
632 mean annual temperatures recorded in the Magdalenian horses are consistent with a climatic amelioration  
633 following the Last Glacial Maximum (Jones et al., 2021).

## 634 5. Conclusions

635 This study provides a comprehensive analysis of the temporal evolution of the environment and climatic  
636 conditions in northern Iberia, spanning from the late Middle Paleolithic to the late Upper Paleolithic, this is  
637 from the GS21 to the GS2, ranging from 80,000 to 15,000 cal BP. In the Vasco-Cantabrian region, the  
638 results reveal a heterogeneous landscape characterised by an open mosaic, ranging from light forest to  
639 meadows and grasslands. This landscape reconstruction is primarily influenced by the feeding locations of  
640 the studied animals and, consequently, related to the ecosystems where hominins captured them. Despite  
641 shifts in niche configuration observed between equids and bovines, both species typically forage in open  
642 areas, with bovines showing a higher preference for grazing. Only in El Castillo, during the late Mousterian  
643 and the Transitional Aurignacian levels, bovines show unusually low  $\delta^{13}\text{C}$  related to higher browsing and  
644 overlapping with horse isotopic niche. This might indicate a slightly closed mosaic landscape that could  
645 sustain both species. In contrast, only horses from Canyars exhibit a preference for grazing behavior.

646 Stable climatic conditions are described for Mousterian Axlor and El Castillo levels from 80,000 to 50,000  
647 BP. However, some elements indicate some environmental perturbations initiated during the Transitional

648 Aurignacian levels from El Castillo, around 48,000 BP and after HE5/GS13. After GS12 (44,200-43,300 BP),  
649 horses and bovines are potentially occupying different ecological niches during the Châteleperronian and  
650 early Aurignacian levels from Labeko Koba, pointing to a species' environmental specialisation, which can  
651 be a consequence of competition for food resources during an unstable ecological period. The climatic  
652 estimations indicate a temperature shift during this period, with a slight decrease in temperatures and  
653 evidence of fluctuations in rainfall from the Transitional Aurignacian levels of El Castillo to the early  
654 Aurignacian levels of Labeko Koba. Previous environmental studies on the region have underlined  
655 ecological stress and aridity increase around 48,000 cal BP, which could sustain this biological  
656 impoverishment. When comparing the environmental conditions during the Aurignacian period in the  
657 Mediterranean (Canyars) and the Vasco-Cantabrian region (Labeko Koba), the Mediterranean area had  
658 higher baseline temperatures but also experienced higher aridity. Animals continued to feed on open  
659 landscapes during the Gravettian and Magdalenian levels in the Vasco-Cantabrian region, represented by  
660 Aitzbitarte III and El Otero sites. However, there is evidence of a temperature recovery after the LGM at the  
661 El Otero site.

662 For the first time, a regional approach is obtained by measuring  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  in enamel carbonates from  
663 ungulates teeth for the late Middle and Upper Paleolithic in northern Iberia. Stable isotope composition of  
664 oxygen and carbon from ungulate teeth has provided valuable insights into the diet and foraging areas of  
665 bovines, equids, and cervids. These results, derived from this extensive sampling in the Vasco-Cantabrian,  
666 establish the basis of stable isotopic studies on teeth enamel, which were slightly explored in the region.  
667 Despite the uncertainties inherent in this work, derived from using the carbonate enamel fraction for  
668 paleoclimatic estimations, both  $\delta^{18}\text{O}$  and  $\delta^{13}\text{C}$  contributed to the regional climatic characterisation, including  
669 the estimation of temperatures and precipitations, as well as the seasonality range between summer and  
670 winter. The potential influence of pretreatment effects and uncontrolled diagenetic alterations on the enamel  
671 carbonate fraction has been assessed. However, further investigation using new techniques like phosphate  
672 analysis and FTIR are needed to gain more insights into sample preservation. Ongoing sulphur, hydrogen  
673 and strontium studies will provide additional information on the animal mobility patterns consumed for  
674 hominins and, therefore, landscape exploitation through this transition between late Neanderthal and early  
675 modern human groups. A more comprehensive characterisation of the baseline oxygen values in the region  
676 would also enhance the environmental interpretation of the existing data.

#### 677 **Appendices**

678 Appendices A, C and D are presented after bibliography. Raw data is found in Appendix B available at  
679 [https://github.com/ERC-Subsilience/Ungulate\\_enamel-carbonate](https://github.com/ERC-Subsilience/Ungulate_enamel-carbonate)

#### 680 **Code availability**

681 R code used to perform plots and models in this manuscript can be accessed at GitHub  
682 ([https://github.com/ERC-Subsilience/Ungulate\\_enamel-carbonate](https://github.com/ERC-Subsilience/Ungulate_enamel-carbonate)).

#### 683 **Data availability**

684 The available datasets used for this article are provided in the supplementary materials (Appendix A-D).

#### 685 **Author contribution**

686 A.B.M.-A. got the funding and designed the research. A.B.M.-A and M.F.-G. get the permissions for sampling  
687 in the regional museums. M.F.-G., K.B. and S.P. defined the analysis strategy. M.F.-G. analysed the data  
688 and wrote the manuscript with critical inputs from A.B.M.-A., K.B. and S.P. J.M.G., L.A., M.F.-G., and A.C.  
689 M.F.-G., L.A., J.M.G., and A.C. achieved the teeth sampling and lab sample preparation. J.D. and M.S. are

690 responsible for the excavations in Canyars and contribute to the discussion. All the authors revised and  
691 commented on the manuscript.

#### 692 **Competing interests**

693 The contact author has declared that none of the authors has any competing interests

#### 694 **Acknowledgments**

695 We acknowledge the Museo de Arqueología y Prehistoria de Cantabria (MUPAC), the Consejería de  
696 Educación, Cultura y Deporte del Gobierno de Cantabria, the Museo de Arqueología de Bizkaia (Arkeologi  
697 Museoa) and the Centro de Colecciones Patrimoniales de la Diputación Foral de Gipuzkoa (Gordailua) -  
698 Provincial Government of Guipuzkoa's Heritage Collection Centre for the access to the archaeological  
699 collections. We do appreciate the work achieved by H. Reade during the initial sampling, pretreatment and  
700 analyses of samples undertaken at the University of Cantabria and Cambridge.

#### 701 **Financial support**

702 Funding for Vasco-Cantabria research was obtained from the Spanish Ministry of Science and Innovation  
703 (PID2021-125818NB-I00, HAR2017-84997-P and HAR2012-33956) and the European Research Council  
704 under the European Union's Horizon 2020 Research and Innovation Programme (grant agreement number  
705 818299; SUBSILIENCE project). Research for Canyars was funded by the Spanish Ministry of Science  
706 and Innovation (PID2020-113960GB-I00), Departament de Cultura de la Generalitat de Catalunya  
707 (CLT/2022/ARQ001SOLC/128) and AGAUR (SGR2021-00337). S.P. was supported by a German  
708 Academy of Sciences Leopoldina postdoctoral fellowship (LPDS 2021-13) during this project. M.S. benefited  
709 from financial support from a Ramon y Cajal postdoctoral grant (RYC2021-032999-I).

928 **Appendix A. Sites description**

929

930 **A1. Vasco-Cantabrian sites**

931 **Axlor (Dima, Vizcaya, País Vasco)**

932 Axlor is a rock-shelter located in Dima (43.2706; -1.8905), with a continuous Middle Paleolithic sequence  
933 from the MIS5 to the MIS3 (DeMuro et al., 2023; Pederzani et al., 2023; Marín-Arroyo et al., 2018). It is  
934 placed on the southwestern slope of the Dima valley, with an elevation of approximately 320 m above sea  
935 level (a.s.l.), at 33 km straight from the present-day coastline, next to one of the lowest mountain passes  
936 linking the Cantabrian basins and the Alavese Plateau. The site was discovered in 1932 and initial  
937 excavations were performed by Barandiarán (1967-1974). J. M. Barandiarán undertook the excavations  
938 between 1967 and 1974, identifying eight Mousterian levels (I-VIII) (Barandiarán, 1980).

939 From 2000 to 2008, new excavations by González-Urquijo, Ibáñez-Estévez and Rios-Garaizar were  
940 achieved and, since 2019, these are ongoing by González-Urquijo and Lazuén. Due to the lack of  
941 chronology during Barandiarán excavations, among other aspects, work was focused on obtaining a detailed  
942 stratigraphy on the new excavation areas to correlate it with Barandiarán's levels (González-Urquijo &  
943 Ibáñez-Estévez, 2021; González Urquijo et al., 2005). The new stratigraphic sequence is roughly equivalent  
944 to the previous one, but with additional levels, not previously identified or excavated by Barandiarán. Some  
945 of these levels were deposited before Level VIII (Gómez-Olivencia et al., 2018; 2020). The Middle Paleolithic  
946 sequence extends from layers VIII to III (or from N to B-C). Levallois production is predominant in the lower  
947 levels (VI to VIII), while Quina Mousterian technocomplex does in the upper ones (from III to V) (Rios-  
948 Garaizar, 2012, 2017). New chronological data by radiocarbon and OSL methods confirm that a sequence  
949 Axlor levels VI, VIII, and VIII probably accumulated during MIS5d-a (109–82 ka), while levels D to B probably  
950 were formed during the period encompassing the start of MIS 4 (71–57 ka) through to the beginning or  
951 middle of MIS 3 (57–29 ka) (Demuro et al., 2023) and upper Level III to 46,200 ±3,000 BP, which calibrates  
952 between 45,510 cal BP and the end of the calibration curve at > 55,000 cal BP (see Pederzani et al., 2023:  
953 Fig. 1).

954 The archaeozoological study indicate an anthropic origin of the faunal assemblage with scarce carnivore  
955 activity documented (Altuna, 1989; Castaños, 2005; Gómez-Olivencia et al., 2018). In lower layers, the most  
956 abundant taxa are *Cervus elaphus* (VIII) and *Capra pyrenaica* (VII), while in upper layers III-V, *Cervus*  
957 *elaphus* is substituted by *Bos primigenious/Bison priscus* and *Equus sp.* The material included in this work  
958 comes from the faunal collection of the Barandiarán excavation currently curated at the Bizkaia Museum of  
959 Archaeology (Bilbao) where teeth were sampled and the stable isotope analyses on enamel phosphate were  
960 included in Pederzani et al. (2023).

961

962 **El Castillo (Puente Viesgo, Cantabria)**

963 El Castillo is cave located in Puente Viesgo (43.2924; -3.9656), with an elevation of approximately 195m  
964 a.s.l., at 17 km straight from the present-day coastline. The cave belongs to the karstic system that was  
965 formed in the Monte Castillo, which dominates the Pas valley. The site was discovered in 1903 by H. Alcalde  
966 del Río. H. Obermaier carried out the first excavation seasons between 1910 and 1914, when many of the  
967 archeological remains were recovered, mainly from the hall of the cave. These interventions were done  
968 under the supervision of the "Institut de Paléontologie Humaine" (IPH) and of Prince Albert I of Monaco.  
969 From 1980 to 2011; V. Cabrera and F. Bernaldo de Quirós underwent new excavations focusing on the cave  
970 entrance, on the Middle to Upper Paleolithic transitional levels, mainly 16, 18 and 20 (Cabrera-Valdes,  
971 1984). The site has yielded an important stratigraphic sequence, composed by 26 sedimentological units

972 (1-26) related to different anthropic occupational units, often separated by archeologically sterile units:  
973 Eneolithic (2), Azilian (4), Magdalenian (6 and 8), Solutrean (10), Aurignacian (12, 14, 16 and 18),  
974 Mousterian (20, 21 and 22) and Acheulean (24) (Cabrera-Valdés, 1984).

975 Unit 21 is mostly sterile (Cabrera Valdés, 1984; Martín-Perea et al., 2023) and it was dated by ESR yielding  
976 a mean date of  $69,000 \pm 9,200$  years BP (Rink et al., 1997). However, Martín-Perea et al. (2023) suggested  
977 some dating uncertainty arising from the interpretation of the initial stratigraphic nomenclature. They suggest  
978 that the ESR dates provided for level 21 by Rink et al. (1997) were erroneously attributed to this unit and it  
979 might correspond to 20E indicating that below that subunit the chronology is older than 70,000 years BP  
980 (Martín-Perea et al., 2023). The Mousterian Unit 20 cave is divided into several subunits (Martín-Perea et  
981 al., 2023). In Unit 20, a cave roof collapse took place transforming the cave system into an open rock shelter.  
982 This unit contains abundant archaeological and paleontological remains. Lithic industry consistent in  
983 sidescrapers, denticulates, notches and cleavers, the majority on quartzite and presents both unifacial,  
984 bifacial discoid debitage and Levallois debitage. Unit 20E was attributed to Quina Mousterian by Sánchez-  
985 Fernández and Bernaldo De Quiros (2009) and contains a Neanderthal tooth remain (Garraida, 2005).  
986 Considering the geochronological uncertainties for dates on 20E related with Rink et al. (1997), we have  
987 decided to solely rely on ERS date of  $47,000 \pm 9400$  BP provided by Liberda et al. (2010) for this level. Unit  
988 20C presents clear evidence of the Mousterian lithic industry and radiocarbon dates of  $48,700 \pm 3,400$  uncal  
989 BP (OxA-22204) and  $49,400 \pm 3,700$  uncal BP (OxA-22205) (Wood et al., 2018) and mean ESR date of  
990  $42,700 \pm 9900$  BP (Liberda et al., 2010). Level 19 is archaeologically sterile and separates Unit 20 from Unit  
991 18 (Wood et al., 2018).

992 Unit 18 is divided into three parts: 18A (archaeologically sterile), 18B, and 18C. Levels 18B and 18C were  
993 classified as Transitional Aurignacian, representing a gradual transformation from the Mousterian to the  
994 Aurignacian, which is unique to El Castillo cave (Cabrera et al., 2001; Maillou and Bernaldo de Quirós, 2010;  
995 Wood et al., 2018). The dates and the cultural attribution of these levels have been the subject of much  
996 debate (e.g. Zilhao and D'Errico, 2003; Wood et al., 2018). According to Wood et al. (2018), the last dates  
997 of these levels range between  $42,000 \pm 1,500$  uncal BP (OxA-22203) and  $46,000 \pm 2,400$  uncal BP (OxA-  
998 21973), which is much earlier than the start of the Aurignacian period in the Cantabrian region (Marín-Arroyo  
999 et al., 2018; Vidal-Cordasco et al., 2023). The lithic assemblage of Unit 18 appears to be dominated by  
1000 Discoid/Levallois technology (Bernaldo de Quirós and Maillou-Fernández, 2009) but with a high percentage  
1001 of "Upper Paleolithic" pieces. Additionally, punctual bone industry, as well as pieces with incisions and  
1002 engravings, were discovered in Unit 18 (Cabrera-Valdés et al., 2001). Three deciduous tooth crowns  
1003 attributed to Neanderthals were found in Unit 18B (Garraida et al., 2022). Above, Unit 17 is sterile but  
1004 contains scarce lithic and faunal materials, while Level 16 was attributed to the Proto-Aurignacian, with dates  
1005 of  $38,600 \pm 1,000$  uncal BP (OxA-22200) (Wood et al., 2018).

1006 According to Luret et al. (2020), there was a shift in hunting practices between the Late Mousterian (unit 20)  
1007 and the Transitional Aurignacian (unit 18). During the Late Mousterian, hunting strategies were less  
1008 specialized, and the species hunted included red deer, horses, and bovines. However, in Unit 18, a  
1009 specialization in red deer hunting is observed. However, the explanation of this shift has been proposed as  
1010 a response to a cultural choice or induced by climatic changes. The material included in this work comes  
1011 from the faunal collection recovered during the Cabrera-Valdés and Bernaldo de Quirós excavations curated  
1012 at Museo de Prehistoria y Arqueología de Cantabria (MUPAC, Santander).

1013

#### 1014 **Labeko Koba (Arrastre, Guipúzcoa, País Vasco)**

1015 Labeko Koba is a cave located in the Kurtzetxiki Hill (43.0619; -2.4833), at 246 m a.s.l. and 29 km straight  
1016 from the present-day Atlantic coast. In 1987 and 1988, due to the construction of the Arrasate ring road, the

1017 site was discovered and a savage excavation was carried out (Arrizabalaga, 2000a). Unfortunately, the site  
1018 was destroyed after that. The stratigraphic sequence identified nine different levels. The lower Level IX was  
1019 attributed to the Châtelperronian, based on the presence of three Châtelperron points. Although there is a  
1020 lack of human remains in few Cantabrian Châtelperronian sites, recent research has suggested that this  
1021 techno-complex was produced by Neanderthals (Maroto et al., 2012; Rios-Garaizar et al., 2022). Level VII  
1022 marks the beginning of the Aurignacian sequence, likely Proto-Aurignacian, with a lithic assemblage  
1023 dominated by Dufour bladelets (Arrizabalaga, 2000a). Levels VI, V, and IV contain lithic assemblages that  
1024 suggested an Early Aurignacian attribution (Arrizabalaga, 2000b; Arrizabalaga et al., 2009). This site is  
1025 significant because it is one of the few sites with Châtelperronian assemblages and with both Proto-  
1026 Aurignacian and Early Aurignacian separated (Arrizabalaga et al., 2009).

1027 Initial radiocarbon dates were inconsistent with the stratigraphy of the site and much more recent than  
1028 expected for the Early Upper Paleolithic (Arrizabalaga, 2000a). This incoherence was determined to be  
1029 affected by taphonomic alterations (Wood et al., 2014). Later radiocarbon dates undertaken with an  
1030 ultrafiltration pre-treatment provided a new regional framework for the regional Early Upper Paleolithic  
1031 (Wood et al., 2014). The Châtelperronian layer is dated to 38,100±900 uncal BP (OxA-22562) and  
1032 37,400±800 uncal BP (OxA-22560). The Proto-Aurignacian levels cover a period from 36,850±800 uncal  
1033 BP (OxA-21766) to 35,250±650 uncal BP (OxA-21793). The three Early Aurignacian levels are dated to  
1034 35,100±600 uncal BP (OxA-21778) for level VI, ~ 34,000 uncal BP (OxA-21767 and OxA-21779) for level  
1035 V, and ~ 33,000 BP (OxA-21768 and OxA-21780) for level IV (Arrizabalaga et al., 2009).

1036 Taphonomic studies indicate an alternation in the use of the cave between carnivores and humans, the latter  
1037 ones during short occupation periods (Villaluenda et al., 2012; Rios-Garaizar et al., 2012; Arrizabalaga et  
1038 al., 2010). Labeko Koba is considered to have functioned as a natural trap where carnivores, mainly hyenas,  
1039 accessed to animal carcasses. At least in the base of Labeko Koba IX, carnivore activity was higher, and  
1040 they would have consumed the same prey as humans (Villaluenga et al., 2012). The presence of humans  
1041 is linked to strategic use as a campsite associated with a small assemblage of lithic artifacts. The most  
1042 consumed species by Châtelperronian groups were red deer, followed by the consumption of large bovids,  
1043 equids, and woolly rhinoceros. During the Aurignacian period, there was some stability in human  
1044 occupations, although still alternated with carnivore occupations (Arrizabalaga et al., 2010). Cold-adapted  
1045 fauna such as reindeer and woolly rhinoceros were identified in association with the Châtelperronian.  
1046 Reindeer were still present during the Aurignacian levels, as well as the woolly mammoth and arctic fox.  
1047 The original sampling of the studied teeth by this work was performed in the San Sebastian Heritage  
1048 Collection headquarters where the Guipuzcoa archaeological materials were deposited at that time.

1049

#### 1050 **Aitzbitarte III (Renteria, Guipúzcoa, País Vasco)**

1051 Aitzbitarte III is an archaeological site located within a karstic system comprising of nine caves in Renteria  
1052 (43.270; -1.8905). The cave is situated 220 m.a.s.l. and is 10 km away from the present-day coastline. Initial  
1053 archaeological interventions were carried out at the end of the 19th century by P.M. de Soraluce (Altuna,  
1054 2011). Recent excavations were initially conducted in the deep zone inside the cave between 1986 and  
1055 1993, and later focused on the cave entrance between 1994 and 2002, by J. Altuna, K. Mariezkurrena, and  
1056 J. Rios-Garaizar (Altuna et al., 2011; 2017).

1057 While the cave's entrance area contains a sequence comprising Mousterian, Evolved Aurignacian, and  
1058 Gravettian layers (Altuna et al., 2011; 2013), the stratigraphy in the inner cave presents 8 levels: level VIII  
1059 (some tools with Mousterian features), VII (sterile), VIb, VIa and V (Middle Gravettian technocomplex with  
1060 abundance of Noailles burins), IV-II (disturbed archaeological levels) and I (surface) (Altuna et al., 2017).  
1061 Levels V have dates of 24,910 uncal BP (I-15208) and 23,230 uncal BP (Ua-2243); whereas level VI extends

1062 from  $23,830 \pm 345$  uncal BP (Ua-2628) and  $25,380 \pm 430$  uncal BP (Ua-2244) (Altuna, 1992; Altuna et al.,  
1063 2017), with a possible outlier dated at 21,130 uncal BP (Ua-1917).

1064 The Gravettian occupation in the inner part of the cave was originally thought to be more recent than the  
1065 ones in the cave entrance. However, it was difficult to correlate the two excavation areas due to different  
1066 sedimentation rates. The rich human occupations took place during a singular cold phase in the Middle  
1067 Gravettian with a specialized paleoeconomy focused on the hunting of *Bos primigenius* and *Bison priscus*  
1068 (85% in level VI and 68% in level V), which is unusual in the Cantabrian region mostly focused on red deer  
1069 and ibex. Other ungulates present are *Cervus elaphus* and *Rupicapra rupicapra*, and to a lesser extent  
1070 *Capra pyrenaica*, *Capreolus capreolus*, *Rangifer tarandus*, and *Equus ferus* (Altuna et al., 2017; Altuna &  
1071 Mariezkurrena, 2020). There is a scarce representation of carnivores. The tooth studied was sampled at the  
1072 Gordailua Center for Heritage Collections of the Provincial Council of Gipuzkoa.

1073

#### 1074 **El Otero (Secadura, Voto, Cantabria)**

1075 El Otero cave is located in Secadura (Voto) (43.3565; -3.5360), at 129 m.s.a.l and 12 km straight from the  
1076 present-day coastline. Near the Matienzo valley in a coastal plain environment covered by meadows and  
1077 gentle hills. The discovery was made in 1908 by Lorenzo Sierra. The site was excavated in 1963 by J.  
1078 Gonzalez Echegaray and M.A. Garcia Guinea, in two different sectors (Sala I and Sala II) with an equivalent  
1079 stratigraphic sequence (González Echegaray, 1966). A total of nine levels were identified in Sala I, from  
1080 level IX to level I. Levels IX and VIII were originally related to the “Aurignacian-Mousterian, based on lithics  
1081 assemblages with a combination of both technocomplex features. The overlying levels VI-IV were separated  
1082 by a speleothem crust (level VII) and were initially related to Aurignacian, due to the presence of end-  
1083 scrappers, bone points, blades, or burins on truncation (Freeman, 1964; Rios-Garaizar, 2013). Also,  
1084 perforated deer, ibex, and fox teeth were found in levels V and IV. This site lacked chronological dating  
1085 methods, until a selection of material from levels VI, V and IV revealed a difference chrono-cultural attribution  
1086 (Marín-Arroyo et al., 2018). Radiocarbon results yielded younger dates for such a cultural attribution and  
1087 show significant stratigraphic inconsistency. Level VI gave a result of  $12,415 \pm 55$  (OxA-32585), two dates in  
1088 Level V are  $12,340 \pm 55$  (OxA-32509) and  $10,585 \pm 50$  (OxA-32510) and a date in Level IV is  $15,990 \pm 80$   
1089 (OxA-32508). All these results fall into the range of the Late Upper Paleolithic (Magdalenian-Azilian initially  
1090 identified in levels III-I), eliminating attribution of these levels to the Aurignacian, despite the presence of  
1091 apparently characteristic artefacts.

1092 Red deer dominate the assemblage, except for level IV where horses are more abundant. Wild boar, roe  
1093 deer, and ibex are also present, but large bovids are relatively rare (González Echegaray, 1966). Level IV  
1094 is the richest and most anthropogenic level, with evidence of butchering in red deer (captured in winter and  
1095 early summer) and chamois (in autumn) The formation of this level involved humans and carnivores, and  
1096 although certain data may suggest an anthropogenic predominance, the limited sample analyzed  
1097 taphonomically and the pre-selection of preserved pieces do not allow for a definitive conclusion (Yravedra  
1098 & Gómez-Castanedo, 2010). The material included in this work is curated at the Museo de Prehistoria y  
1099 Arqueología de Cantabria (MUPAC, Santander).

1100

#### 1101 **A2. Mediterranean sites**

##### 1102 **Terrasses de la Riera dels Canyars (Gavà, Barcelona, Cataluña)**

1103 Terrasses de la Riera dels Canyars (henceforth, Canyars) is an open-air site located near Gavà (Barcelona)  
1104 (41.2961; 1.9797), at 28 m.s.a.l and 3 km straight from the present-day coastline. The site lies on a fluvial  
1105 terrace at the confluence of Riera dels Canyars, a torrential stream between Garraf Massif, Llobregat delta

1106 and Riera de Can Llong (Daura et al., 2013). Archaeo-paleontological remains were discovered during  
1107 quarries activities in 2005 and was complete excavated on 2007 by the *Grup de Recerca del Quaternari*  
1108 (Daura and Sanz, 2006; Daura et al., 2013). This intervention determined nine lithological units. The  
1109 paleontological and archaeological remains come exclusively from one unit, the middle luthitic unit (MLU),  
1110 and specifically from layer I. The MLU is composed of coarse sandy clays and gravels, filling a paleochannel  
1111 network named lower detrital unit (LDU) (Daura et al., 2013). Five radiocarbon dates were obtained on  
1112 charcoals from layer I, which yield statistically consistent ages from 33,800 ±350 uncal BP to 34,900 ±340  
1113 uncal BP, which results in mean age of 39,600 cal BP (from 37,405 to 40,916 cal BP) (Daura et al., 2013).

1114 The layer I of the site has yielded a rich faunal assemblage, consisting of over 5,000 remains. Among the  
1115 herbivores, the most common species found are *Equus ferus*, *Bos primigenius*, *Equus hydruntinus*, and  
1116 *Cervus elaphus* (Daura et al., 2013; Sanz-Royo et al., 2020). *Capra* sp. and *Sus scrofa* are also present,  
1117 although in lower frequencies. The carnivores found at the site are also noteworthy, with *Crocuta crocuta*  
1118 and *Lynx pardinus* being the most frequent. Presence of cold-adapted fauna associated to stepped  
1119 environments is recorded, such as cf. *Mammuthus* sp., *Coelodonta antiquitatis*, and *Equus hydruntinus*.  
1120 Small mammal analysis, pollen, and use-wear analysis have provided further evidence that a steppe-  
1121 dominated landscape surrounded the Canyars site, supporting a correlation with the Heinrich Event 4, in  
1122 coherence with the chronology obtained for the layer (López-García et al. 2013; 2023; Rivals et al., 2017).  
1123 However, the presence of woodland is also attested by forest taxa within charcoal and pollen assemblages  
1124 (Daura et al., 2013).

1125 Taphonomic study is ongoing. But several evidences point that hyenas have played an important role in the  
1126 accumulation of the faunal assemblage (Daura et al., 2013; Jimenez et al. 2019). However, sporadic human  
1127 presence is documented by few human modifications found in faunal remains (cutmarks and fire alterations).  
1128 Although the paucity of the lithic assemblage in the site, it shows a clear attribution to Upper Palaeolithic  
1129 technocomplex, most likely the Early Aurignacian (Daura et al., 2013). Recently, it was documented a  
1130 perforated bone fragment, which has been identified as a perforated board for leather production (Doyon et  
1131 al., 2023). All teeth included in this work were sampled in *Laboratori de la Guixera* (Ajuntament de  
1132 Castelfelfels) where the material is stored.

1309 **Appendix D. Inverse Modelling: Methodological Details and Models**

1310 The intratooth  $\delta^{18}\text{O}$  profiles presented in this study were obtained through the application of inverse  
1311 modelling, using an adapted version of the code published in reference (Passey et al., 2005). This modeling  
1312 approach allowed for the correction of the damping effect and the reconstruction of the original  $\delta^{18}\text{O}$  input  
1313 time series. The model utilizes different species-specific parameters related to enamel formation, which vary  
1314 between bovines and equids. These parameters have been established based on previous studies (Bendrey  
1315 et al., 2015; Blumenthal et al., 2014; Kohn, 2004; Passey and Cerling, 2002; Zazzo et al., 2012). For  
1316 Bos/Bison sp., the initial mineral content of enamel is fixed at 25%, the enamel appositional length is set at  
1317 1.5 mm, and the maturation length is 25 mm. For *Equus* sp., the initial mineral content of enamel is fixed at  
1318 22%, the enamel appositional length is set at 6 mm, and the maturation length is 28 mm.

1319 In addition, the model requires other variables related to sampling geometry, as well as error estimates  
1320 derived from mass spectrometer measurements. The distance between samples varies for each tooth, but  
1321 as a general trend, the sampling depth on the tooth enamel surface in the samples of this study represents  
1322 approximately 70% of the total enamel depth. The standard deviation of the measurements obtained from  
1323 the mass spectrometer was typically set at 0.12%, taking into account the uncertainty associated with the  
1324 standards. Finally, the models require a damping factor that determines the cumulative damping along the  
1325 isotopic profile by adjusting the measured error (E<sub>meas</sub>) to the prediction error (E<sub>pred</sub>). In the teeth analysed  
1326 in this study, the damping factor ranged from 0.001 to 0.1. The most likely model solutions were selected,  
1327 and summer and winter values were extracted from the  $\delta^{18}\text{O}$  profiles, considering the original peaks and  
1328 troughs identified in the unmodelled  $\delta^{18}\text{O}$  profile. This approach was adopted to prevent the introduction of  
1329 artificial peaks that the model may produce, particularly in teeth without a distinct sinusoidal shape.
