Supplement of

Molecular-level carbon traits of fine roots: unveiling adaptation and decomposition under flooded condition

Mengke Wang et al.

Text S1 Root sample collection

For soil-grown fine roots (SGR), surface soil (approximately 0–20 cm) at the tree base was carefully excavated to expose the primary lateral roots following the procedure described by Guo et al. (2008). For and water-grown fine roots (WGR), whole root systems growing in water were collected. Root branches with intact terminal branch orders were cut, and over 50 g of total fresh biomass of the first three-order roots was obtained from each tree. The function of the first three-order roots is mainly resource absorption (McCormack et al., 2015), and the "fine roots" in this study refer to these absorptive fine roots of the first three orders. Subsamples of the fine roots separated from the root systems were gently washed in low-temperature deionized water to remove soil adhering to the roots.

Text S2 Sequential extraction procedure and GC-MS quantification

Solvent extraction for the dichloromethane and methanol extractable fraction (F_{DcMe}) was performed with 100.0 mg of homogenized root samples (R1), which was extracted with 15 mL dichloromethane (DCM), methanol (MeOH): DCM (1:1, v/v), and MeOH consecutively in 50 mL fluorinated ethylene propylene (FEP) tubes via ultrasonication for 15 min on an ultrasonic instrument (ANPEL 2400TH; frequency of 40 kHz) at 20°C. After centrifugation (3000 g for 5 min), the combined solvent extracts were concentrated via rotary evaporation and filtered through a 0.45 μm polyether sulfone filter. The filtrates were dried under N_2 gas in 2 mL glass vials. The remaining samples (non-extractable residues, R2) were air-dried, weighed, and stored at –20°C.

For the base-hydrolyzable fraction (F_{KOHhy}), subsamples of the solvent-extracted residues (R2) were hydrolyzed with 15 mL of freshly prepared 1 mol·L^{-1} methanolic KOH in hydrothermal reactors with 20 mL polytetrafluoroethylene (PTFE) cups at 100°C for 3 h. After cooling to 20°C, the contents were centrifuged, and the supernatants were allowed to evaporate, then they were acidified to pH < 1. The hydrolyzable products were liquid−liquid extracted with 30 mL ethyl acetate three times. The extracts were then concentrated via rotary evaporation and dried under N_2 gas in 2 mL glass vials. The remaining samples (R3) were air-dried, weighed, and stored at −20°C.

For the CuO-oxidizable fraction (F_{CuOox}), subsamples after the base hydrolysis (R3) were oxidized with 1 g CuO, 100 mg Fe(NH$_4$)$_2$(SO$_4$)$_2$·6H$_2$O, and 15 mL of 1 mol·L^{-1} NaOH (pre-sparged with N_2 for 5 min) in PTFE-lined reactors at 170°C for 2.5 h. After cooling to room temperature (20°C), the reaction products were centrifuged; the supernatants were then allowed to evaporate, acidified to pH < 1, and kept in the dark for at least 1 h. The lignin phenols were liquid−liquid extracted with 30 mL ethyl acetate three times. The extracts were then concentrated and dried under N_2 gas in 2 mL glass vials. The remaining samples (R4) were washed with 0.01 mol·L^{-1} HCl to remove any excess CuO and then rinsed with deionized water to remove excess HCl, followed by freeze-drying, weighing, and storing at −20°C.

Aliquots of F_{DcMe} and F_{CuOox} were trimethylsilyl derivatized with *N,O*-bis(trimethylsilyl)trifluoroacetamide (BSTFA) at 70°C for 1 h. An aliquot of F_{KOHhy} was first methylated with *N,N*-dimethylformamide dimethyl acetal (DMF-DMA) at 60°C for 0.5 h and then trimethylsilyl derivatized. After derivatization, all compounds were analyzed using an Agilent 7890B gas chromatograph equipped with a 5977B mass spectrometer using an HP-5MS column (30 m × 0.25 mm i.d., film thickness, 0.25 μm). The injection volume was 1 μL, and the injection temperature was 300°C. The oven temperature was programmed from 60 to 300°C at a rate of 6°C·min^{-1} and held at 300°C for 20 min. The compounds of F_{DcMe} and F_{KOHhy} were detected in scan mode, with the mass scan range from 50 to 550 Da. F_{CuOox} compounds were detected in selected ion mode based on the method of Kaiser and Benner (2012). For F_{DcMe}, a mixed standard of tetracosane, 1-docosanol, methyl tricosanoate, and ergosterol was used. For aliphatics in F_{KOHhy}, a mixed standard of methyl tricosanoate and methyl oleate was used. For phenolics in F_{KOHhy} and F_{CuOox}, a mixed standard containing a total of 11 lignin phenols (including *p*-hydroxybenzoic acid (PAD), *p*-hydroxyacetophenone (PON), *p*-hydroxybenzaldehyde (PAL), vanillic acid (VAD), acetovanillone (VON), vanillin (VAL), syringic acid (SAD), acetosyringone (SON), syringaldehyde (SAL), *p*-coumaric acid (CAD), and ferulic acid (FAD)) was used.

Also, the total carbon content of root samples (R1) and residues after dichloromethane and methanol extraction (R2), base hydrolysis (R3), and CuO oxidation (R4; Figure 1) were determined using a Vario MACRO cube elemental

63 analyzer (Elementar, Hanau, Germany). Root ash content was determined as the remaining proportion of root mass

64 after burning at 550°C in a muffle furnace for 4 h.

Figure S1 One of the mature trees of *Dysoxylum binectariferum* Hook. f growing by a slow flowing stream and its soil-grown (SGR) and water-grown fine roots (WGR). WGR had observably different morphology, such as larger diameter and less branches. These photographic materials were taken by Mengke Wang.
Figure S2 Solid-state ^{13}C cross-polarization magic angle spinning nuclear magnetic resonance integration results for SGR (a) and WGR (b) samples before and during sequential extraction with a variety of extraction procedures. Bars represent mean ± standard error (n = 3). Different letters at the top of each bar indicate significant differences ($P <$ 0.05) in percentages of carbon regions among different solid phases after sequential extraction. Four colors from light to dark indicate original fine-root samples (R1) and residues after solvent extraction (R2), base hydrolysis (R3), and CuO oxidation (R4). The carbonyl and carboxyl C, O-aromatic C, aromatic C, di-O-alkyl C, O-alkyl C, N-alkyl/methoxy C, and alkyl C are restricted within chemical shifts (ppm) of 165−210, 145−165, 110−145, 95−110, 60−95, 45−60, and 0−45, respectively.
Figure S3 Fourier transform ion cyclotron resonance mass spectra (FT-ICR MS) of the different extractable fractions of organic matter in three replicates of f soil-grown roots (SGR, a-i) and water-grown roots (WGR, j-r). F_{DcMe}: dichloromethane and methanol extractable fractions; F_{KOHhy}: base-hydrolyzable fractions; F_{CuOox}: CuO-oxidizable fractions.

14
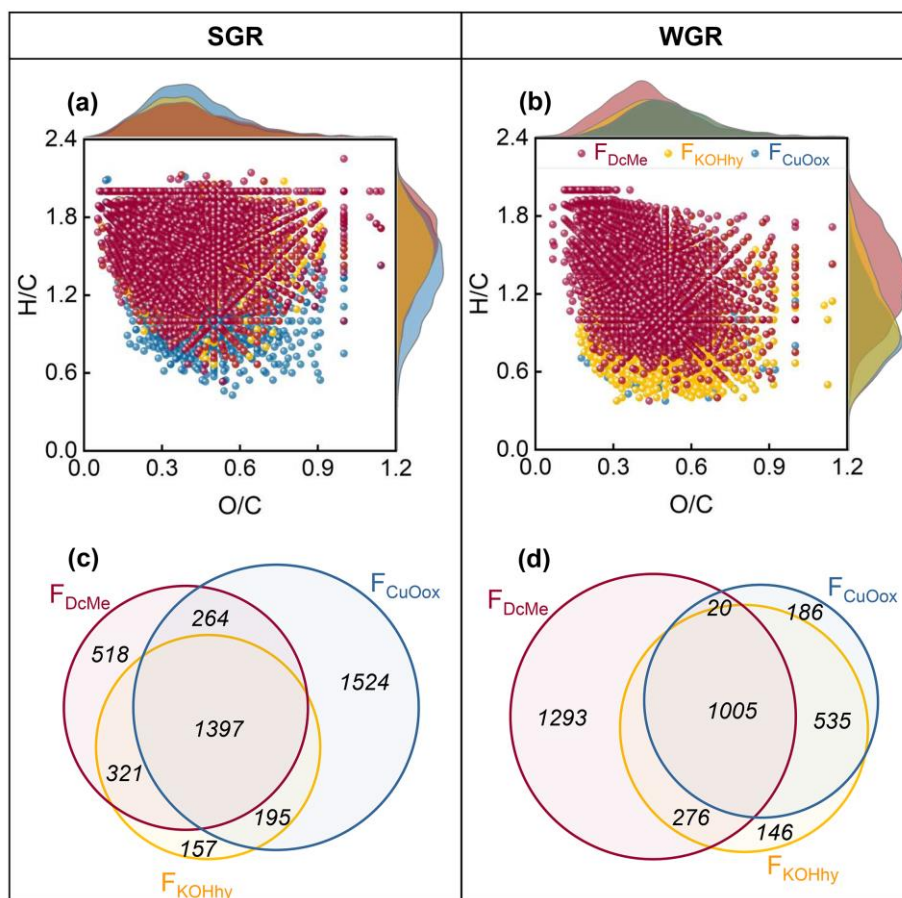

Figure S4 van Krevelen and Venn diagrams of Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR MS)-detected formulae from sequentially extracted fractions of soil-grown roots (SGR; a, c) and water-grown roots (WGR; b, d). F_{DcMe}: dichloromethane and methanol extractable fractions; F_{KOHhy}: base-hydrolyzable fractions; F_{CuOox}: CuO-oxidizable fractions. Note that the formulae in van Krevelen diagrams (**a, b**) are the common formulae existing in all three replicates, and the percentage of number and signal of these common formulae in the total number and total signal were on average 76% and 90%, respectively (Table S3).
