15 Abstract

16 The assessment of cropland carbon and nitrogen (C & N) balances play a key role to identify  
17 cost effective mitigation measures to combat climate change and reduce environmental  
18 pollution. In this paper, a biogeochemical modelling approach is adopted to assess all C & N  
19 fluxes in a regional cropland ecosystem of Thessaly, Greece. Additionally, the estimation and  
20 quantification of the modelling uncertainty in the regional inventory are realized through the  
21 propagation of parameter distributions through the model leading to result distributions for  
22 modelling estimations. The model was applied on a regional dataset of approximately 1000  
23 polygons deploying model initializations and crop rotations for the 5 major crop cultivations  
24 and for a timespan of 8 years. The full statistical analysis on modelling results (including the  
25 uncertainty ranges given as  $\pm$  values) yields for the C balance carbon input fluxes into the soil  
26 of  $12.4 \pm 1.4$  tons C ha<sup>-1</sup> yr<sup>-1</sup> and output fluxes of  $11.9 \pm 1.3$  tons C ha<sup>-1</sup> yr<sup>-1</sup>, with a resulting  
27 average carbon sequestration of  $0.5 \pm 0.3$  tons C ha<sup>-1</sup> yr<sup>-1</sup>. The averaged N influx was  $212.3 \pm$   
28  $9.1$  kg N ha<sup>-1</sup> yr<sup>-1</sup> while outfluxes were estimated on average of  $198.3 \pm 11.2$  kg N ha<sup>-1</sup> yr<sup>-1</sup>. The  
29 net N accumulation into the soil nitrogen pools was estimated to  $14.0 \pm 2.1$  kg N ha<sup>-1</sup> yr<sup>-1</sup>. The  
30 N outflux consist of gaseous N fluxes composed by N<sub>2</sub>O emissions  $2.6 \pm 0.8$  kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup>  
31 <sup>1</sup>, NO emissions of  $3.2 \pm 1.5$  kg NO-N ha<sup>-1</sup> yr<sup>-1</sup>, N<sub>2</sub> emissions  $15.5 \pm 7.0$  kg N<sub>2</sub>-N ha<sup>-1</sup> yr<sup>-1</sup> and  
32 NH<sub>3</sub> emissions of  $34.0 \pm 6.7$  kg NH<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, as well as aquatic N fluxes (only nitrate leaching  
33 into surface waters) of  $14.1 \pm 4.5$  kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, N fluxes of N removed from the fields in  
34 yields, straw and feed of  $128.8 \pm 8.5$  kg N ha<sup>-1</sup> yr<sup>-1</sup>.

## 44 1 Introduction

45 Food security as well as the agricultural productivity depend to a major extent on the applied  
46 nitrogen (N) fertilizers (Klatt et al., 2015a). Worldwide, the N fertilizer use for the years 1960 to  
47 2005 has increased from 30 to 154 million tons (IFADATA, 2015). In Europe, the increase of  
48 yields in arable land and grassland systems was 45-70% since 1950 (EFMA, 2009) due to the  
49 agricultural production systems intensification. Excessive use of N fertilizers, though  
50 beneficially affecting the yield, could cause a harmful impact to the environment, e.g. increased  
51 gaseous emissions and aquatic fluxes of nitrous oxide (N<sub>2</sub>O) to the atmosphere and leaching  
52 of nitrate (NO<sub>3</sub>) into water bodies (Erisman et al., 2011; Galloway et al., 2013; Kim et al., 2015)  
53 The N<sub>2</sub>O poses a twofold environmental threat. From the one hand, it is a strong greenhouse  
54 gas with a warming potential of 300 times greater (in a 100-year time period) than carbon  
55 dioxide (CO<sub>2</sub>) and from the other hand, it is a major driver of ozone depletion in stratosphere  
56 (Ravishankara et al., 2009). The fertilizer use aiming at the increase of the agricultural  
57 production is the most crucial anthropogenic source of atmospheric N<sub>2</sub>O, which at present  
58 contributes for approximately 45% of total anthropogenic N<sub>2</sub>O emissions on a global scale  
59 (Jones et al., 2014). Because of the global population growth and thus a growing food and  
60 feed demand (Godfray et al., 2010), the fertilizer use will probably increase. Consequently, the  
61 prediction of the current business-as-usual scenarios show doubled anthropogenic N<sub>2</sub>O  
62 emissions by the year 2050 (Davidson and Kanter, 2014). The European countries have  
63 recently set up bilateral agreements in order to reduce N<sub>2</sub>O emissions from cultivated crop  
64 lands (EU-Commission, 2014). Similarly, the European Nitrates Directive (EU-Commission,  
65 2019; Musacchio et al., 2020) aims at NO<sub>3</sub> leaching reduction to water bodies to avoid both an  
66 increase of eutrophication (Camargo and Alonso, 2006) and drinking water pollution. Because  
67 of the hazardous N<sub>2</sub>O and NO<sub>3</sub> effects, agricultural systems are necessary to be evaluated for  
68 their profitability and productivity as well as for their impacts to the environment.

69 The N<sub>2</sub>O and NO<sub>3</sub> production and consumption in agricultural lands are regulated to a large  
70 extent by N plant uptake and, also, the microbial processes of denitrification and nitrification  
71 (Butterbach-Bahl et al., 2013). The factors controlling both the microbial metabolism and plant

72 N uptake are a) soil conditions (Butterbach-Bahl et al., 2013) and b) cultivation management  
73 practices e.g. crop rotation, fertilizing amount and timing, and ploughing (Smith et al., 2008).  
74 In order to reach a minimization of the environmental footprint of agricultural production while  
75 securing the global food security (Garnett et al., 2013), it is mandatory to tighten the N cycling  
76 on intensified agricultural systems e.g., by harmonizing N demand of crops with soil N  
77 availability by N fertilization.

78 Full nitrogen balance inventories provide a comprehensive understanding of the different N  
79 input and output fluxes within an arable system to the scientific community, farmers and policy  
80 makers. The assessment of the N balance is essential to optimize nitrogen use and production  
81 and minimize environmental impact and pollution. Especially policy making and regulatory  
82 bodies require accurate and robust information on all different nitrogen fluxes to develop  
83 effective strategies in agricultural N management. Up to now, our understanding of N cycling  
84 in arable land lacks observations of the full N balance as only few studies tried to quantify the  
85 total N balance of agricultural systems, e.g. (Zistl-Schlingmann et al., 2020) using stable  
86 isotope techniques or (Schroeck et al., 2019) using process based modelling.

87 A recent opinion paper by a large group of leading scientists Grosz et al., (2023) in the field of  
88 process based ecosystem modelling identified the lack of knowledge on the full N balance and  
89 “the scarcity of complete modeled N balances in the literature stems from the reluctance of the  
90 scientific community to support the publication of unvalidated modeled results, especially given  
91 that the simulation results of these neglected N pools and fluxes may be unrealistic. This this  
92 self-censorship of authors has resulted in a missed opportunity to share knowledge and  
93 improve our understanding of modeled processes.”

94 Grosz et al., (2023) conclude that “including the entire N balance and related should become  
95 standard when publishing the results of N model studies.” Grosz et al., (2023) emphasize that  
96 this would allow to assess the robustness of modelled N fluxes and full N balances, and to  
97 illustrate the diversity and uncertainty of the different process based modeling approaches,  
98 e.g. modelling denitrification processes in soils.

99 In this analysis, the process-based bio-geochemical model LandscapeDNDC (Haas et al.,  
100 2013) was applied to the agricultural cropland systems in the region of Thessaly (Greece). The  
101 objective of our study was threefold:

102 i) Assessing and reporting the cropland C and N balance including all associated  
103 fluxes such as e.g. CO<sub>2</sub>, N<sub>2</sub>O and NH<sub>3</sub> emissions, NO<sub>3</sub> leaching as well as the soil  
104 carbon stock changes as demanded by Grosz et al., (2023).

105 ii) Increasing the robustness and trustworthiness of the balance modelling by  
106 assessing and quantifying the modelling uncertainty of the simulated C and N  
107 balance and flux estimations as requested before by the IPCC (IPCC, 2019)

108 iii) Presenting a regional uncertainty assessment methodology for C and N cycling to  
109 advance the balance modelling by propagating 500 joint parameter and input data  
110 distributions through the model (each representing a full regional C and N balance  
111 inventory simulation) yielding regional result distributions for any modelling  
112 estimations.

113

## 114 2 Material and Methods

### 115 2.1 Model description

116 LandscapeDNDC is a modular process-based ecosystem model for simulating the bio-  
117 geochemical change of C and N in croplands, forest and grassland systems at both site and  
118 regional scale. The modules combined are about plant growth, micro-meteorology, water  
119 cycling, physico-chemical-plant and microbial C and N cycling and exchange processes with  
120 atmosphere and hydrosphere of terrestrial ecosystems. LandscapeDNDC is a generality of the  
121 plant development and soil biogeochemistry of the agricultural DNDC and Forest-DNDC (Li,  
122 2000). There is a successful application of earlier model versions in a number of studies, e.g.  
123 water balance (Grote et al., 2009; Holst et al., 2010), plant growth (Cameron et al., 2013;  
124 Werner et al., 2012), NO<sub>3</sub> leaching (Kim et al., 2015; Thomas et al., 2016) and soil respiration  
125 and gas emission trace (Chirinda et al., 2011; Kraus et al., 2014; Molina-Herrera et al., 2015).

126 For the initialization of LandscapeDNDC physical and chemical site-specific soil profile  
127 information is used (specified for different soil depths): Soil organic carbon (SOC) and nitrogen  
128 (SON) content, soil texture (clay, sand and silt content), of the plant growth and soil  
129 biogeochemistry, bulk density, pH value, saturated hydraulic conductivity, field capacity and  
130 wilting point. Daily or hourly climate data of air temperature (max, min and average), N  
131 deposition, precipitation, and atmospheric CO<sub>2</sub> concentration are used in LandscapeDNDC in  
132 combination with agricultural management practices e.g. crop planting and harvesting,  
133 fertilizing (synthetic and organic) or feed cutting and tilling are used to drive LandscapeDNDC  
134 simulations. Regarding fertilization management three types of mineral fertilizers, i.e. urea,  
135 compound fertilizers based on NH<sub>4</sub> and NO<sub>3</sub> as well as organic amendments, i.e. green  
136 manure, farmyard manure, slurry, straw, bean cake and compost are currently considered.  
137 The growth of crops and grasses is similar to the DNDC approach using two major parameters  
138 that describe seasonal plant development (cumulative temperature degrees days) and  
139 maximum reachable biomass under optimum conditions (Li, 2000) while daily growth  
140 limitations due to water and nutrient availability are considered. Model parameters describing  
141 soil and vegetation characteristics are obtained from an external parameter library. In  
142 LandscapeDNDC, the parameterization of the main cultivated commodity crops in Europe  
143 occurs by default parameter sets representing an average plant type while process parameter  
144 values for micro-meteorology, water cycle and bio-geochemical processes were obtained from  
145 previous validation studies, e.g. (Klatt et al., 2015a; Molina-Herrera et al., 2016; Rahn et al.,  
146 2012) proving that the LandscapeDNDC model could be universally applicable for similar  
147 conditions.

148 For all simulations in the current study, site-specific crop parameterizations were derived in a  
149 preceding analysis of various site scale simulations and validations of yield characteristics  
150 across the region. An overview of the crops cultivated at the different study sites and detailed  
151 information on specific crop rotations used to simulate crop growth are provided in Table A2  
152 (supplementary material).

## 153 2.2 Case study description and input data

154 The region of Thessaly is located in Central Greece covering a total area of 14 000 Km<sup>2</sup>, where  
155 5000 Km<sup>2</sup> is lowland and approx. 2300 Km<sup>2</sup> and 6500 Km<sup>2</sup> are semi-mountainous and  
156 mountainous land respectively. The plain of Thessaly is considered to be among the largest  
157 agricultural land of the country (Kalivas et al., 2001) accounting for almost 410 000 ha, of which  
158 about 370 000 ha is arable land where almost 80% is covered by annual and 10% by perennial  
159 crops (ELSTAT, 2012). The crop/plant production of the region is around 14.2% (ELSTAT,  
160 2012) of the total production of the country (2<sup>nd</sup> in Greece).

161 Soil input data for the region was available from the European Project Nitro Europe IP (Sutton  
162 et al., 2013) based on the European Soil Database (ESDB v2.0, 2004) containing, soil type  
163 and soil profile description of bulk density, SOC content, texture (sand, silt clay), pH value,  
164 stone fraction, saturated hydraulic conductivity, wilting point and water-holding capacity in  
165 various soil strata (Cameron et al., 2013). A regional soil dataset for the area of interest  
166 contained about 1500 spatial polygons out of which approximately 1000 covered the cultivated  
167 cropland that was finally simulated. The climate data for the regional simulations was derived  
168 at polygon level from gridded ERA5 climate data for Greece.

## 169 2.3 Agricultural Management and model input data processing

170 The total cultivated area and the respective yields for the years 2010 to 2016, used in the  
171 current analysis were obtained from the Hellenic Statistical Authority (ELSTAT). Moreover,  
172 data associated with the animal capital for the respective years was also provided (ELSTAT)  
173 in order to estimate the annual manure production distributed in the region however no data is  
174 available on whether and how much of the manure is used in croplands. For the water  
175 management, the percentage of irrigated and non-irrigated land (estimated to almost 50% for  
176 each case) was also given (ELSTAT) while indicative sets of irrigation management data were  
177 acquired through the River Basin Management Plans of the Special Secretariat for Water,  
178 Ministry of Environment and Energy (YPEKA, Portmann et al., 2010). The irrigation water  
179 volumes were estimated based on the crops needs and the minimum and maximum quantities

180 necessary according to literature while using upscaling tools to get the regional values. The  
 181 fertilization data sets were provided by Fertilizer Producers and Merchandiser Association  
 182 (FPMA) for the recent years (2010-2016) and are equated to the annual consumed quantities  
 183 on a national level, scaled down to a regional level based on crop pattern in the Region of  
 184 Thessaly cultivated land.

185 In this study, the five main crops maize, wheat, clover, cotton and barley were considered,  
 186 covering the majority of the cultivated arable land in the region (over 95%) while the remaining  
 187 cropland was included acquiring the final corrected land/crop coverage. In Table 1 the resulting  
 188 crop rotation scenarios (R1 - R5) are presented for the evaluation period 2012 - 2016. Note,  
 189 each rotation sequence (R1 – R5) is shifted in time such that for each year, each crop appears  
 190 exactly in one rotation. Based on the crop cover contribution in each simulated year the crop  
 191 rotation contribution factors were estimated and are summarized in Table 2. The management  
 192 practices were based on the general agricultural practices applied in the region and information  
 193 provided by farmers.

194

195 *Table 1. Summary of the crop rotation scenarios (R1- R5) for the region of Thessaly. The crop abbreviations corn,*  
 196 *wiwh, clover, cott and wbar refer to maize (food corn and silage maize), winter wheat, clover (legume feed crops*  
 197 *s.a. alfalfa or vetch), cotton and winter barley respectively.*

year	R1	R2	R3	R4	R5
2012	clover	cotton	wbar	corn	wiwh
2013	cotton	wbar	corn	wiwh	clover
2014	wbar	corn	wiwh	clover	cotton
2015	corn	wiwh	clover	cotton	wbar
2016	wiwh	clover	cotton	wbar	corn

198

199 *Table 2. Crop cultivation area contribution per year to the aggregation of the five rotations; data constant across*  
 200 *the region of Thessaly*

Crop Rotation Contribution [% / 100]					
Years	R1	R2	R3	R4	R5
2012	0.15	0.15	0.45	0.11	0.14
2013	0.13	0.29	0.09	0.10	0.39

2014	0.29	0.13	0.10	0.35	0.12
2015	0.15	0.11	0.43	0.16	0.16
2016	0.10	0.36	0.14	0.14	0.25

202

## 203 2.4 Uncertainty analysis

204 As stated in the IPCC 2006 guidelines and updated in 2019, the assessment of uncertainty is  
 205 considered a major and crucial/mandatory component when compiling regional or national  
 206 GHG emission inventories (Larocque et al., 2008). The difference in scale in which the model  
 207 is used results in divergent errors of the C and N dynamics prediction across different climate  
 208 zones and scales. Thus, uncertainty analysis is a crucial step towards a higher quality decision  
 209 making process. The sources of uncertainty can vary and are related to a) the initial conditions  
 210 (starting values), b) the drivers (e.g. climate and crop management data), c) the conceptual  
 211 model uncertainty and d) the parameter uncertainty of the various processes (Refsgaard et al.,  
 212 2007; Wang and Chen, 2012).

213 Santabárbara, (2019) performed a Bayesian Model Calibration and Uncertainty Analysis using  
 214 a Monte Carlo Markov Chain (MCMC) approach targeting uncertainties associated to the data  
 215 (bulk density, SOC, pH, clay content) of the initial soil conditions, drivers (cropland  
 216 management such as fertilization/manure rates & timing, harvest & seeding timing, tillage  
 217 timing) and bio-geochemical process parameterizations.

218 In order to identify the most sensitive process parameters with a reduced number of model  
 219 simulations, the Morris method (Morris, 1991) obtains a hierarchy of parameters influence on  
 220 a given output (gaseous N fluxes) and evaluates whether a non-linearity exists or not. (Morris,  
 221 1991) proposed that this order can be assessed through the statistical analysis of the changes  
 222 in the model output, produced by the "one-step-at-a-time" changes in "n" number of proposed  
 223 parameters. Incremental steps of each parameter range, lead to identifying which ones have  
 224 substantial influences over the concerned results, without neglecting that some effects could

225 cancel each other (Saltelli et al., 2000), leading to the identification of the 24 most sensitive  
226 process parameters (Houska et al., 2017; Myrgeiotis et al., 2018b).

227

## 228 Metropolis – Hastings algorithm

229 The Markov Chain Monte Carlo (MCMC) Metropolis–Hastings algorithm results in numerous  
230 parameter sets that approximate the posterior joint parameter distribution by performing a  
231 random walk through the space of joint parameter values. This probability evaluation of the  
232 data obtained from each step leads to the update of the initial uniform parameter distributions.  
233 Bayes' formula relating conditional probabilities may become a powerful and practical  
234 computational tool when combined with Markov chain processes and Monte Carlo methods,  
235 so-called Markov Chain Monte Carlo (MCMC). A Markov chain is a special type of discrete  
236 stochastic processes wherein the probability of an event depends only on the event that  
237 immediately precedes it. Integrating parameters ( $\theta$ ) and observation data ( $D$ ) into Bayes' rule  
238 results in the formula:

239

$$P(\theta|D) = \frac{P(D|\theta) * P(\theta)}{P(D)} \quad 2.1$$

240 where  $P(D|\theta)$ , the probability of the data, is used to obtain the probability of these parameters  
241 updated by the data:  $P(\theta|D)$  where the evidence is computed as:

242

$$P(D) = \int \text{likelihood} \cdot \text{prior} \cdot d\theta \quad 2.2$$

243 where  $P(D)$  can be numerically approximated with the aforementioned MCMC method (Robert  
244 and Casella, 2011).

245 The method uses prior knowledge concerning the sources of the model uncertainty to obtain  
246 a narrowed posterior distribution for each one of the sources. By propagating the parameter  
247 distributions through the model, the overall uncertainty in the model results can be quantified.

248 In a previous study by Santabárbara, (2019), an extensive sensitivity analysis on all soil bio-  
249 geochemical process parameters, soil initial data and arable management data was performed  
250 identifying the 24 most sensitive process parameters (listed in supplementary material), the  
251 most sensitive soil initial data (soil profile data on bulk density, soil organic carbon content, pH  
252 value) and the most sensitive management information (fertilization and manure N rates, tilling  
253 depth) to aquatic and gaseous N fluxes from arable soils. This was digested in the MCMC  
254 simulation sampling a combination of 24 parameter values, 3 values of soil initial data and 3  
255 management information. The sampling of the soil initial data as well as the management data  
256 was performed as perturbations to the existing data: For each quantity, a perturbation was  
257 sampled individually and applied to all corresponding values in the soil profile or to all years in  
258 the management description. The MCMC simulation performed by Santabárbara, (2019)  
259 simulated more than 100 000 iterations for various arable sites until the MCMC simulation  
260 converged towards a stable combined posterior distribution of parameter values and soil and  
261 management input data perturbations. In the current analysis, we have sampled 500 joint  
262 parameter / input data perturbation sets from the posterior distributions as reported by  
263 Santabárbara, (2019) and we deployed them in simulations (propagation through the model)  
264 for the regional inventory leading to 500 inventory simulations. A statistical analysis was,  
265 afterwards, applied to estimate the updated regional and temporal result distributions.

266

## 267 2.5 Statistical methods and data aggregation

### 268 Regional result aggregation

269 One full regional inventory simulation consists of 10 individual inventory simulations: Five (5)  
270 different crop rotations for irrigated and rain feed conditions were simulated in parallel (see  
271 section 2.3). The results of the crop rotations were aggregated according to the crop shares  
272 per year (see Table 2) accounting for all effects of the different crops cultivated in the region  
273 for irrigated and rain feed conditions. The final inventory simulation results were obtained by  
274 considering irrigated versus rain feed water management. The final inventory contains

275 simulation results aggregated to area weighted yearly means across the total simulation  
276 domain accounting for the cropland area of each polygon.

277

## 278 Uncertainty quantification and statistical analysis

279 A regional aggregation was performed for all 500 uncertainty simulations. All the uncertainty  
280 results were finally reported via statistical measures evaluating the 500 regional uncertainty  
281 simulation runs reporting mean values, standard deviation, medians and the 25 and 75  
282 interquartile ranges (IQR, Q25 to Q75).

283

## 284 3 Results Analysis and Evaluation

285 The simulation time span was from 2009 to 2016, while the years 2009 – 2011 were used as  
286 spin-up to get all soil C and N pools into equilibrium after the initialization. Therefore, reported  
287 simulation results are limited to years 2012 - 2016. The assessment of the regional C and N  
288 balances (CB and NB) were obtained - as a consequence of the uncertainty quantification -  
289 resulting in distributions and therefore reported by statistical measures such as mean/median  
290 or interquartile ranges of the uncertainty ensemble.

291

### 292 3.1 Regional yield simulations and validation

293 The evaluation of the model performance in estimating the NB and CB components was  
294 analyzed based on the comparison of the simulated yield values with the observed yield data  
295 provided by the Hellenic Statistical Authority (ELSTAT), averaged for the total simulated  
296 period.

297

298 Crop yields and feed production

299 For model validation, datasets of crop yields from Hellenic Statistical Authority (ELSTAT) were  
 300 used. Table 3 summarizes the aggregated regional crop yields for all the simulated years and  
 301 the respective mean, median and standard deviation values resulted from the statistical  
 302 analysis of the simulation results together with the observed yield and feed production provided  
 303 by the Hellenic Statistical Authority (ELSTAT). Simulated yields consist for cotton of the cotton  
 304 bolls, clover feed is the total cutting and harvested above ground biomass, for wheat and barley  
 305 is the grain yield and for maize is accounted grain ear and the stems. Based on the  
 306 observations, maize appears to be the dominant crop with an average yield of 12 tons ha<sup>-1</sup>,  
 307 followed by clover product of 8.4 tons ha<sup>-1</sup>. The rest of the three crop yields appear to be in the  
 308 same order of magnitude from 3.3 up to 3.4 tons ha<sup>-1</sup>.

309

310 *Table 3. Simulated and observed yields and feed production [tons dry matter ha<sup>-1</sup>] in the region of Thessaly. All*  
 311 *results are based on statistical aggregation across all polygons, rotations, years and finally across all 500 UA*  
 312 *inventory simulations. The observed values of dry matter (DM) are provided by the Hellenic Statistical Authority.*

Simulated crop yield and feed distributions [tons dry matter ha <sup>-1</sup> ]				Observed [tons dry matter ha <sup>-1</sup> ]
Crops	Median	Mean	standard deviation	Mean
Cotton	3.5	3.3	0.8	3.3
Clover	9.8	9.6	0.6	8.4
Wheat	3.9	3.6	0.9	3.4
Barley	4.7	4.5	1.0	3.3
Maize <sup>1)</sup>	10.2	9.9	1.4	12.0

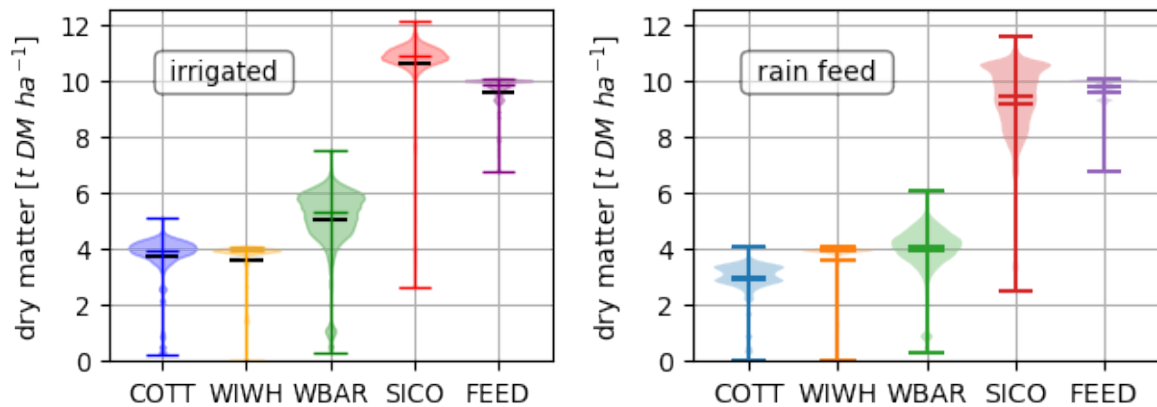

313 <sup>1)</sup> Observation data for maize did not distinguish between food corn and silage maize.

314

315 Additionally, the simulated average yield of cotton was estimated to 3.3 ± 0.8 tons DM ha<sup>-1</sup>,  
 316 wheat to 3.6 ± 0.9 tons DM ha<sup>-1</sup>, barley 4.5 ± 1 tons DM ha<sup>-1</sup>, maize 9.9 ± 1.4 tons DM ha<sup>-1</sup>. As  
 317 for the feed, the clover was estimated to 9.6 ± 0.6 tons DM ha<sup>-1</sup>. The average nitrogen use  
 318 efficiency (NUE) across time and space is 63.29%.

319

320 Figure 1 presents the uncertainties of the simulated crop yield across the whole evaluation  
 321 time span 2012 -2016 both in irrigated and rain feed conditions. As shown, corn shows a much  
 322 more narrow distribution with a higher median for the irrigated scenario compared to the rain  
 323 feed while shows the same extreme value variations. To the contrary, winter barley has a wider  
 324 distribution and slightly higher median for the irrigated scenario and, also, a wider extreme  
 325 value variation. As for cotton, the distribution appears to be bimodal for the rain feed scenario  
 326 in which the median is also lower than the one in the irrigated case. In addition, the extreme  
 327 value variation is wider in the latter case. Finally, for the example of winter wheat irrigated and  
 328 rain feed scenarios reach the same results.  
 329

330  
 331 *Figure 1. Simulated crop yield uncertainties across the evaluation time span 2012 - 2016 for irrigated and rain feed*  
 332 *conditions. Horizontal lines indicate median, mean, maximum and minimum values of the distributions.*

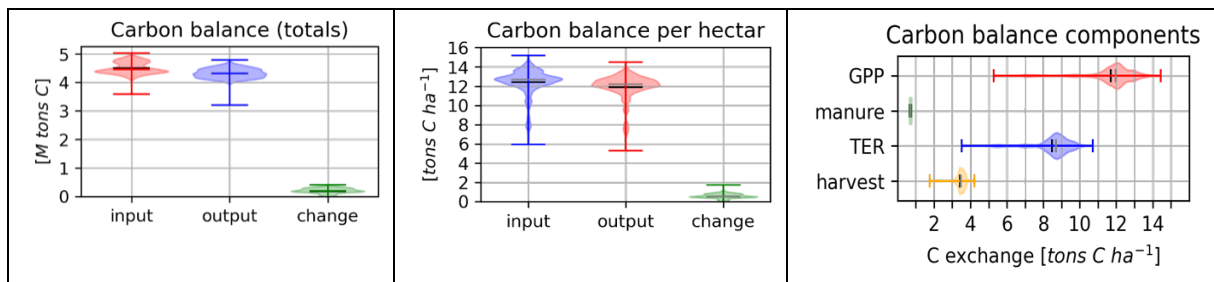

333

### 334 3.2 Regional Carbon and Nitrogen Balance

#### 335 Carbon Balance (CB)

336 For the CB, Figure 2 presents average C input fluxes into the soil of  $12.4 \pm 1.4$  tons C ha<sup>-1</sup> yr<sup>-1</sup>  
 337 <sup>1</sup> (with inter quartile ranges (IQR) from Q25 to Q75 of 12.1 to 13.2 tons C ha<sup>-1</sup> yr<sup>-1</sup>) and output  
 338 fluxes of  $11.9 \pm 1.3$  tons C ha<sup>-1</sup> yr<sup>-1</sup> with IQR from 11.6 to 12.7 tons C ha<sup>-1</sup> yr<sup>-1</sup>. The resulting  
 339 carbon sequestration was estimated to  $0.5 \pm 0.3$  tons C ha<sup>-1</sup> yr<sup>-1</sup> with IQR from 0.4 to 0.7 tons  
 340 C ha<sup>-1</sup> yr<sup>-1</sup> (data summarized in Table 4).

341

342 *Figure 2. Carbon balance for cropland cultivation for the region of Thessaly: a) Total carbon balance of cropland*  
 343 *soils in mio. tons C, b) averaged Carbon Balance in tons C ha<sup>-1</sup> and c) averaged fluxes across the region and the*  
 344 *years 2012-2016. (Positive change equals soil C sequestration).*

345

346 The input fluxes consist of annual gross primary productivity (GPP) of  $11.7 \pm 1.4$  tons C ha<sup>-1</sup>  
 347 yr<sup>-1</sup> with IQR from 11.4 to 12.4 tons C ha<sup>-1</sup> yr<sup>-1</sup> and carbon applied to soils in manure estimated  
 348 by  $0.7 \pm 0.001$  tons C ha<sup>-1</sup> yr<sup>-1</sup> (see Table 4). This compares on the other hand to respirative  
 349 carbon fluxes from the soil to the atmosphere (TER) of  $8.5 \pm 1.1$  tons C ha<sup>-1</sup> yr<sup>-1</sup> with IQR from  
 350 8.2 to 9.1 tons C ha<sup>-1</sup> yr<sup>-1</sup> and carbon fluxes via exported crop yields and feed (including all  
 351 straws and removed crop residues) of  $3.4 \pm 0.3$  tons C ha<sup>-1</sup> yr<sup>-1</sup> with IQR from 3.4 to 3.6 tons  
 352 C ha<sup>-1</sup> yr<sup>-1</sup>. The aggregation of the carbon fluxes to the regional level of approx. 360 000 ha of  
 353 cropland results in  $4.25 \pm 0.20$  M tons C yr<sup>-1</sup> by GPP,  $0.25 \pm 0.01$  M tons C yr<sup>-1</sup> carbon influx  
 354 via organic fertilizers compared to  $3.08 \pm 2.97$  M t C yr<sup>-1</sup> TER and  $1.24 \pm 0.05$  M t C yr<sup>-1</sup> carbon  
 355 exports via crop yields and feed production leading to a net carbon sequestration of  $0.5 \pm 0.3$   
 356 M tons C ha<sup>-1</sup> yr<sup>-1</sup> with IQR from 0.4 to 0.7 M tons C ha<sup>-1</sup> yr<sup>-1</sup> (M tons C as Million tons carbon).

365

### 366 Nitrogen balance (NB)

367 In Figure 3 the assessment of the distribution of the NB with the in- and out-fluxes is presented.

368 The averaged nitrogen influx (represented by the uncertainty ensemble mean) per hectare was

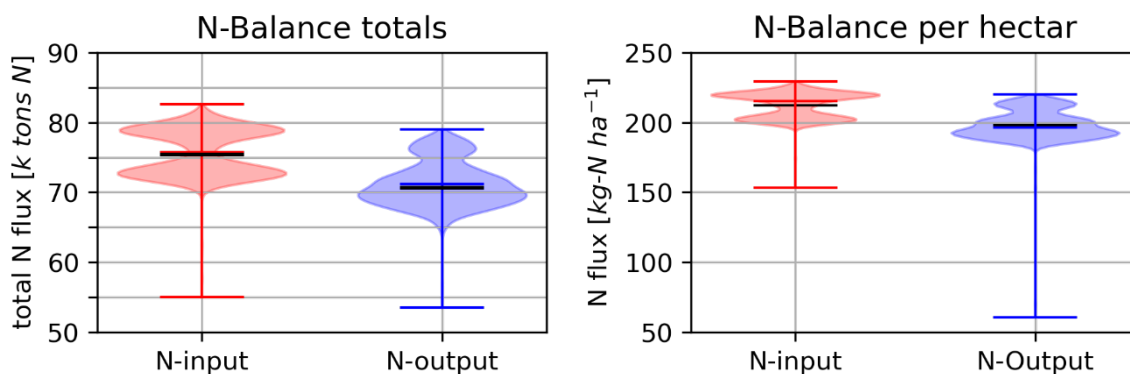

369 estimated to  $212.3 \pm 9.1$  kg N ha<sup>-1</sup> yr<sup>-1</sup> with IQR from 203.3 to 220.0 kg N ha<sup>-1</sup> yr<sup>-1</sup> while nitrogen

370 out-fluxes were estimated in average to  $198.3 \pm 11.2$  kg N ha<sup>-1</sup> yr<sup>-1</sup> with IQR from 191.4 to

371 204.0 kg N ha<sup>-1</sup> yr<sup>-1</sup> (Figure 3) leading to a net N accumulation in the soil of  $14.0 \pm 2.1$  kg N ha<sup>-1</sup>

372 yr<sup>-1</sup> with IQR from 11.9 to 16.0 kg N ha<sup>-1</sup> yr<sup>-1</sup>.

373

374

375 *Figure 3. Nitrogen balance for cropland cultivation for the region of Thessaly; a) Total NB in k-tons N and b)*

 380 *(per hectare) of cropland cultivation of the region of Thessaly, Greece. <sup>1)</sup> N-Inputs as the sum of the absolute values*  
 381 *of all input fluxes of the 500 simulations; <sup>2)</sup> N-Outputs as the sum of the absolute values of all the output fluxes of*  
 382 *the 500 simulations; <sup>3)</sup> N-stock-changes as the difference between the input and output fluxes of each of the 500*  
 383 *simulations; <sup>4)</sup> Gaseous emissions are the sum of N<sub>2</sub>O, NO, N<sub>2</sub> and NH<sub>3</sub> fluxes; <sup>5)</sup> Aquatic flux is nitrate leaching*  
 384 *(NO<sub>3</sub><sup>-</sup>).*

	Mean	Std	Median	Q25	Q75
	[kg N ha <sup>-1</sup> yr <sup>-1</sup> ]	[kg N ha <sup>-1</sup> yr <sup>-1</sup> ]	[kg N ha <sup>-1</sup> yr <sup>-1</sup> ]	[kg N ha <sup>-1</sup> yr <sup>-1</sup> ]	[kg N ha <sup>-1</sup> yr <sup>-1</sup> ]
N-Inputs <sup>1)</sup>	212.3	9.1	215.2	203.3	220.0
N-Outputs <sup>2)</sup>	198.3	11.2	196.4	191.4	204.0
N-stock-changes <sup>3)</sup>	13.8	2.1	13.7	14.5	12.5
Input fluxes					
N deposition	6.3	0.8	6.8	6.0	6.8
Bio. N fixation	45.6	4.3	45.7	43.7	47.7
N in min. fertilizer	80.2	4.8	81.3	76.6	82.7
N in organic fertilizer	80.2	3.6	80.9	77.5	82.7
Output fluxes					
Gaseous emissions <sup>4)</sup>	55.4	8.8	55.1	48.9	61.6
N <sub>2</sub> O	2.6	0.8	2.5	2.1	3.1
NO	3.2	1.5	2.9	2.0	4.1
N <sub>2</sub>	15.5	7.0	14.6	9.9	20.7
NH <sub>3</sub>	34.0	6.7	31.8	29.3	36.9
Aquatic fluxes <sup>5)</sup>					
NO <sub>3</sub> leaching	14.1	4.5	13.6	11.0	17.0

385  
 386 The N influx was composed by the input of synthetic fertilizer of 80.2 ± 4.8 kg N ha<sup>-1</sup> yr<sup>-1</sup> (IQR  
 387 76.6 to 82.7) and organic fertilizer of 80.2 ± 3.6 kg N ha<sup>-1</sup> yr<sup>-1</sup> (IQR from 77.5 to 82.7), followed  
 388 by the biological nitrogen fixation (BNF) via legumes estimated as 45.6 ± 4.3kg N ha<sup>-1</sup> yr<sup>-1</sup> (IQR  
 389 from 43.7 to 47.7) and nitrogen deposition of 6.3 ± 0.8kg N ha<sup>-1</sup> yr<sup>-1</sup> (IQR from 6.0 to 6.8). Thus,  
 390 almost 75% of the nitrogen input influx is related to the fertilization (mineral and organic) whilst  
 391 the minor part that corresponds to nitrogen fixation and deposition approximates to 25%.

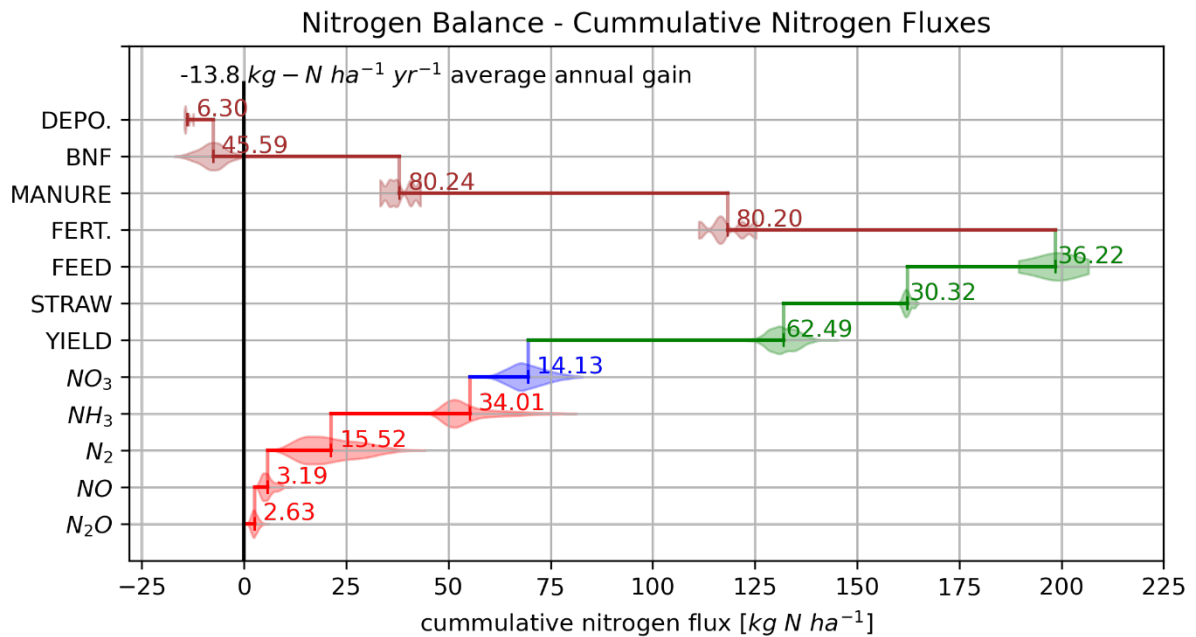

392 The N outflux consist of gaseous N fluxes of  $55.4 \pm 8.8 \text{ kg N ha}^{-1} \text{ yr}^{-1}$  (IQR from 48.9 to 61.6),  
 393 aquatic N fluxes (only nitrate leaching into surface waters was considered) of  $14.1 \pm 4.5 \text{ kg N}$   
 394  $\text{ha}^{-1} \text{ yr}^{-1}$  (IQR from 11.0 to 17.0), N fluxes by removed N in yields, straw and feed of  $128.8 \pm$   
 395  $8.5 \text{ kg N ha}^{-1} \text{ yr}^{-1}$  (IQR of 125.2 to 131.7) (see Figure 4 and Table 5). Based on the  
 396 aforementioned results all gaseous and aquatic N-fluxes correspond to about 28% and 7% of  
 397 the N output flux respectively, while the far largest N output flux was N removed in yields, straw  
 398 and feed representing almost 65% of the N outflux (Figure 4).

399  
 400 *Figure 4. Averaged annual nitrogen balance (inner ring of the pie diagram) and their decomposition into the various*  
 401 *components of the N fluxes (outer ring of the pie diagram); (all data summarized in Table 5).*

402  
 403 The simulated gaseous fluxes were composed of  $\text{N}_2\text{O}$  emissions estimated to  $2.6 \pm 0.8 \text{ kg}$   
 404  $\text{N}_2\text{O-N ha}^{-1} \text{ yr}^{-1}$  (IQR from 2.1 to 3.1), NO emissions of  $3.2 \pm 1.5 \text{ kg NO-N ha}^{-1} \text{ yr}^{-1}$  (IQR from  
 405 2.0 to 4.1),  $\text{N}_2$  emissions  $15.5 \pm 7.0 \text{ kg N}_2\text{-N ha}^{-1} \text{ yr}^{-1}$  (IQR range from 9.9 to 20.7) and  $\text{NH}_3$   
 406 emissions of  $34.0 \pm 6.7 \text{ kg NH}_3\text{-N ha}^{-1} \text{ yr}^{-1}$  (IQR from 29.3 to 36.9). Ammonia volatilization  
 407 represents the largest share (61.48%) of gaseous N losses, with highest densities in the  
 408 emission distribution between approx. 25 and 35  $\text{kg N ha}^{-1}$ , followed by di-nitrogen losses

409 (28.03%) of gaseous N losses, with a much wider emission variability in the distribution,  
 410 followed by  $\text{NO}_3$  (5.79%) and  $\text{N}_2\text{O}$  (4.7%). Figure 5 shows the overall NB in a waterfall diagram  
 411 adding up cumulative all in- and out-fluxes illustrating the uncertainty distribution of each flux  
 412 contributions. The waterfall diagram illustrates the overall outcome of the NB, a N accumulation  
 413 into the soil as the difference between all out-fluxes minus all in-fluxes.  
 414

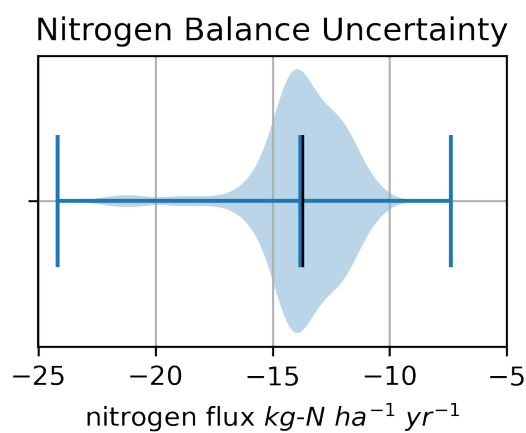

415  
 416 *Figure 5. Waterfall representation of the result distributions of the different Nitrogen in- and outfluxes of the cropland*  
 417 *cultivation in Thessaly. Vertical lines in the distributions indicate mean values of the corresponding N-flux. Red*  
 418 *colors indicate gaseous outfluxes, blue aquatic fluxes, green biomass yield and feed production outfluxes and brown*  
 419 *color indicates N influxes such as synth. N-fertilizer, N-Manure, biological N fixation (BNF) and N deposition. The*  
 420 *Resulting N sink of the Nitrogen Balance (based on distribution means) is  $-13.8 \text{ kg N ha}^{-1} \text{ yr}^{-1}$ . (Negative value*  
 421 *indicates flux into the soil).*

422  
 423 Nitrate leaching mean estimates were  $14.1 \pm 4.5 \text{ kg NO}_3\text{-N ha}^{-1} \text{ yr}^{-1}$  (IQR from 11.0 to 17.0)  
 424 with a bell-shaped distribution.  
 425 Total yield and biomass (straw and feed) N export fluxes were  $62.4 \pm 4.4 \text{ kg N ha}^{-1} \text{ yr}^{-1}$  with  
 426 uncertainty ranges from 59.9 to 65.1 consisting of yield N exports (grains and cotton balls) of  
 427  $30.3 \pm 1.7 \text{ kg N ha}^{-1} \text{ yr}^{-1}$  (IQR from 29.6 to 30.9) and for straw and feed N exports of  $36.1 \pm 6.0$   
 428  $\text{kg N ha}^{-1} \text{ yr}^{-1}$  (IQR from 34.9 to 37.6). The result distributions for yield N are well bell shaped,

429 for feed biomass N very moderate bell shaped and well distributed within the bounds and for  
430 straw N very sharp within a comparable small interval.

431 Figure 5 illustrates the cumulative nitrogen fluxes composing the NB as a waterfall diagram  
432 considering the mean of each component. The NB results in a net N sink of 13.8 kg N ha<sup>-1</sup> yr<sup>-1</sup>  
433 <sup>1</sup> (see result distribution in Figure 6) for the region corresponding to an annual carbon  
434 sequestration of approx. 0.5 tons C ha<sup>-1</sup> yr<sup>-1</sup> as depicted in Figure 2 b) (see also the annual  
435 dynamics of the topsoil (30 cm) soil organic carbon and nitrogen distributions in Figure 8).

451 *(subfigure b)) and the corresponding dynamics of the uncertainty distributions of the annual change rates of the*  
452 *total soil carbon and nitrogen pools (subfigures c) and d)) respectively.*

#### 453 4 Discussion.

454 In this study, following the recommendation of Grosz et al., (2023), an assessment of the  
455 combined full C and N balance of a regional cropland agroecosystem is reported for the first  
456 time using inventory simulations with a process-based ecosystem model. The additional  
457 quantification of the associated modelling uncertainty of the balance simulations increase the  
458 trustworthiness of the study.

459 Up to present, process-based modelling studies mainly focus on single site applications e.g.  
460 Daycent: (del Grosso et al., 2005; Gurung et al., 2020), APSIM: (Vogeler et al., 2013), CERES-  
461 EGC: (Dambreville et al., 2008; Gabrielle et al., 2006; Heinen, 2006; Hénault et al., 2005),  
462 CERES-Wheat: (Mavromatis, 2016), DNDC: (Li, 2000), LandscapeDNDC: (Haas et al., 2013;  
463 Klatt et al., 2015a; Molina-Herrera et al., 2016; Zhang et al., 2015). Fewer studies deploy  
464 models on the regional to national (del Grosso et al., 2005; Kim et al., 2015; Klatt et al., 2015a)  
465 or continental to global scale (del Grosso et al., 2009; Franke et al., 2020; Jägermeyr et al.,  
466 2021; Smerald et al., 2022; Thompson et al., 2019). All of these studies are subject to criticism  
467 stated by Grosz et al., (2023) **as they are reporting** in general only one specific or a few  
468 components of the carbon or nitrogen cycle such as e.g. soil carbon stocks or N<sub>2</sub>O emissions,  
469 lacking any information on the full C and N balance.

470 There are only a very few cases where an attempt for regional estimation of the NB has been  
471 made. The study reported by Schroeck et al., (2019) is the only previous attempt fulfilling the  
472 requirements of Grosz et al., (2023) in reporting the full NB for a large alpine watershed in the  
473 Austrian Alps characterized by arable production in the low-lying areas and grassland in the  
474 mountains using a process based model. In addition, Lee et al., (2020) tried to estimate  
475 nitrogen balances in Switzerland alternating the cropping systems or management practices.  
476 There were, also, cases where the regional NB was estimated with the use of nitrogen balance  
477 equations (He et al., 2018). Recently, Zistl-Schlingmann et al., (2020) assessed the full N  
478 balance of alpine grasslands using the <sup>15</sup>N stable isotope techniques.

479 In order to achieve a more concrete and complete analysis of the CB and NB that could be  
480 used for future policy development, an uncertainty analysis is considered as  
481 necessary/mandatory. The IPCC guidelines demand for UNFCCC reporting the uncertainty  
482 quantification of any reported inventory study (IPCC Updated guidelines 2019). Recent  
483 publications have reported the deployment of different methods to assess and quantify the  
484 various sources of uncertainty in ecosystem modelling. (Klatt et al., 2015b) published a study  
485 on the impact of parameter uncertainty on N<sub>2</sub>O emissions and NO<sub>3</sub> leaching on the regional  
486 scale. (Houska et al., 2017) deployed the GLUE method (Generalized Likelihood Uncertainty  
487 Estimation) for the LandscapeDNDC model on a grassland site, other studies such as  
488 (Lehuger et al., 2009a; Li et al., 2015; Myrriotis et al., 2018a) used the Bayesian Model  
489 Calibration and Uncertainty Assessment approach, which has been used in the current study  
490 as well.

491

#### 492 4.1 Yield and feed Production

493 LandscapeDNDC was validated in a study by Molina-Herrera et al., (2016) on cropland and  
494 grassland sites across Europe reporting good agreement in reproducing observed above  
495 ground biomass and yield estimates. Similar model performance for the cultivation of  
496 commodity crops was reported by (Kasper et al., 2019; Klatt et al., 2015a; Molina-Herrera et  
497 al., 2017; R. J. Petersen et al., 2021).

498 Lyra and Loukas, (2021) used REPIC model to estimate the crop growth/yield production of  
499 several crops in the Basin of Almyros, Thessaly. The simulated results were approximately 11  
500 tons ha<sup>-1</sup> clover, 3.3/3.5 tons ha<sup>-1</sup> cereals/wheat, 3.8 tons ha<sup>-1</sup> cotton and 9 tons ha<sup>-1</sup> maize,  
501 being well compared to the results of our research shown in Table 3. The simulated results  
502 presented in our study are in line with the results by Voloudakis et al., (2015) simulating cotton  
503 production in seven different areas of Greece applying the AquaCrop model. Similar results  
504 were reported by (Tsakmakis et al., 2019).

505 There are few cases in literature concerning yield simulations on a European level. Based on  
506 the yield datasets of FAO and EUROSTAT, Ciaia et al., (2010a) estimated mean crop yields  
507 for the period 1990–1999 at the scale of EU-25 as 6.1 (FAO) and 5.3 (EUROSTAT) tons DM  
508  $\text{ha}^{-1} \text{yr}^{-1}$ , respectively, which corresponds well to results of our study. Haas et al., (2022)  
509 estimated with a model ensemble mean for crop yields for EU-27 of  $4.41 \pm 1.85$  tons DM  $\text{ha}^{-1}$   
510  $\text{yr}^{-1}$  for the period 1990–1999. Lugato et al., (2018) estimated cropland yield projections of  
511 4.34 tons DM  $\text{ha}^{-1} \text{yr}^{-1}$  (mean), ranging from 3.69 to 4.90 tons DM  $\text{ha}^{-1} \text{yr}^{-1}$  with the DayCent  
512 model for EU-27, comparable to the 6.18 tons DM  $\text{ha}^{-1} \text{yr}^{-1}$  average simulated crop yields of  
513 this study. The simulated yields in the current study vary from 3.3 to 9.9 tons DM  $\text{ha}^{-1} \text{yr}^{-1}$  for  
514 the cases of cotton and maize respectively.

515 Higher yield estimates for the region of Thessaly in this study are certainly due to the inclusion  
516 of the legume feed crops in the rotations. This argument is supported by a recent meta-analysis  
517 by (Lu, 2020) that concluded that on average yield increases of 5.0 to 25% can be expected  
518 for various conditions if residues are completely returned to the field as compared to no-residue  
519 return systems. Similar results were reported by Fuchs et al., (2020) and Barneze et al., (2020).  
520 Following the recommendations of Grosz et al., (2023), our study has reported transparently  
521 all major C & N fluxes for the region as being simulated by the model. In our study, we have  
522 not calibrated the model against any observations, therefore all simulation results will be  
523 discussed versus other modelling results available. As up to now, there is only one comparable  
524 modelling study available in literature reporting and discussing the total N balance of a site or  
525 region, which we have used to compare our N balance against.

526

## 527 4.2 Carbon and Nitrogen Balance:

### 528 Full N balance

529 At present, the studies of Schroeck et al., (2019) and Lee et al., (2020) are the only to be found  
530 by Web of Science under the search key words “nitrogen AND balance AND process AND  
531 based AND modelling” reporting a compilation of the nitrogen balance and all associated N

532 fluxes for a site or region applying a process-based ecosystem model as demanded by Gosz  
533 et al (2023).

534 Leip et al., (2011) reported the first nitrogen balance for Europe following a mixed approach  
535 combining the CAPRI (Common Agricultural Policy Regionalised Impact) model (a global  
536 economic model for agriculture) with different approaches estimating various nitrogen fluxes  
537 in arable land cultivation, but the approach lacks the explicit quantification of the different  
538 gaseous N fluxes. The study of Schroeck et al., (2019) overcame this hurdle and applied the  
539 process-based ecosystem model LandscapeDNDC to estimate the full regional nitrogen  
540 budgets including all fluxes of different ecosystems (cropland, grassland and pastures) and  
541 climatic zones of a water shed in Austria. That has been the first attempt estimating and  
542 reporting all the N fluxes possible as demanded by Gosz et al (2023).

543 The N balance estimate in Schroeck et al., (2019) for a catchment in Austria and the N balance  
544 reported in our study compares very well despite the inherent differences in land management  
545 and N inputs. As highlighted by Grosz et al., (2023), such intercomparisons demonstrate the  
546 different model behaviours when applied to different ecosystem. In our study, we see the  
547 partitioning of the N outfluxes from our arable system in similar shares as reported by Schroeck  
548 et al., (2019) for the arable land.

549 The N<sub>2</sub>O estimate in Schroeck et al., (2019) and the current study is of a comparable level. We  
550 estimated N<sub>2</sub>O emissions of 2.6 kg N ha<sup>-1</sup> yr<sup>-1</sup> while Schroeck et al., (2019) reports 1.51 kg N  
551 ha<sup>-1</sup> yr<sup>-1</sup>, about 40% lower. The NO fluxes differ significantly since we reported a mean value  
552 of 3.2 kg NO-N ha<sup>-1</sup> yr<sup>-1</sup> while Schroeck et al., (2019) reports 0.08 kg NO-N ha<sup>-1</sup> yr<sup>-1</sup>. This is  
553 on one hand related to some recent model advances, which have been made during this study,  
554 which elevated the NO production in LandscapeDNDC (Molina-Herrera et al., 2017) and on  
555 the other hand due to the high share of organic N fertilization in our study fostering NO  
556 emissions. Ammonia volatilization differs substantially between the two studies, while our study  
557 reports 34 kg NH<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, Schroeck et al., (2019) reported moderate emissions of 0.23 kg  
558 NH<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>. The strong NH<sub>3</sub> volatilization in our study is mostly driven by the high pH-  
559 values of the soils in the region of Thessaly (pH values from 6.5 to 8.2 with a considerable

560 spatial variation, Greek Soil Map, 2015) and the comparable high manure inputs into the arable  
561 system in our study, while in the research of Schroeck et al., (2019) the manure was preferably  
562 applied only to the grassland systems and mineral fertilizers to the arable land. Concerning  
563 the  $\text{NO}_3$ , Schroeck et al., (2019) reported  $45.3 \text{ kg NO}_3\text{-N ha}^{-1} \text{ yr}^{-1}$  which was 3 times higher  
564 compared to this study ( $14.1 \text{ kg N ha}^{-1} \text{ yr}^{-1}$ ) considering the N-input of approximately 160 kg  
565 and  $212.3 \text{ kg N ha}^{-1} \text{ yr}^{-1}$  respectively. Even though 50 % of the arable land in our study was  
566 irrigated, the resulting water percolation rates in our study were by far lower than the  
567 percolation simulated in the study of Schroeck et al., (2019) as the Austrian pre-alpine  
568 catchment received nearly double annual precipitation.

569 The N balance modelling study of Lee et al., (2020) was estimating for Switzerland a national  
570 cropland N balance using an upscaling method based on process-based site simulations with  
571 the DayCent model differentiating the management of the considered cropping systems e.g.  
572 fertilizer rates, tillage or land cover change. The study reported for conventional cultivations  
573 (averaged across 20 years) yield related N outfluxes accounting for about 60%,  $\text{NO}_3$  leaching  
574 36.1% and gaseous N emissions 4.1% of the total N outputs. Lee et al., (2020) did not report  
575 the different gaseous N fluxes, even though the DayCent model must have simulated all of  
576 them. Although the yield related N outflux is in accordance with our result of 64.95% there  
577 seems to be a discrepancy in the reported gaseous and aquatic N fluxes contribution, as we  
578 report 27.94% for gaseous and 7.11% for  $\text{NO}_3$  leaching in our study. As demanded by Gosz  
579 et al (2023) we can elaborate different preferences in simulated N outflux partitioning (36%  
580  $\text{NO}_3$  and 4% gaseous losses for DayCent versus 7%  $\text{NO}_3$  and 28% gaseous losses for  
581 LandscapedDNDC) due to the different simulation models, regionalization and upscaling  
582 approaches as well as due to the different soil, climatic and management conditions included  
583 in the respective studies.

584 Velthof et al., (2009) used the MITTERA-EUROPE model/method, based on the concoction of  
585 GAINS and CAPRI models, to estimate N fluxes of European soils on NUTS2 scale with the  
586 use of European datasets and literature coefficients, where the fertilizer application and  
587 management was similar to our methodology. The average N Input-Output balance was

588 calculated as 117 kg N ha<sup>-1</sup> yr<sup>-1</sup> composed by manure of 49 kg N ha<sup>-1</sup> yr<sup>-1</sup>, synthetic fertilizer of  
589 58 kg N ha<sup>-1</sup> yr<sup>-1</sup> (in the current study for both cases 80.2 kg N ha<sup>-1</sup> yr<sup>-1</sup>), biological nitrogen  
590 fixation of 2 kg N ha<sup>-1</sup> yr<sup>-1</sup> (our research 45.6 kg N ha<sup>-1</sup> yr<sup>-1</sup>) and N deposition of 7 kg N ha<sup>-1</sup>  
591 (current study 6.3 kg N ha<sup>-1</sup> yr<sup>-1</sup>). In contrast to our study the reported output fluxes for NH<sub>3</sub> of  
592 8 kg NH<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, N<sub>2</sub>O of 2 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup>, NO<sub>x</sub> of 2 kg NO<sub>x</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, N<sub>2</sub> of 51 kg N<sub>2</sub>-N  
593 ha<sup>-1</sup> yr<sup>-1</sup> and NO<sub>3</sub> leaching of 7 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup> while the differences with the results presented  
594 in our study are NH<sub>3</sub> of 34.0 kg NH<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, N<sub>2</sub>O of 2.6 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup>, NO<sub>x</sub> of 3.2 kg  
595 NO<sub>x</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, N<sub>2</sub> of 15.5 kg N<sub>2</sub>-N ha<sup>-1</sup> yr<sup>-1</sup> and NO<sub>3</sub> leaching of 14.1 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>.  
596 Additionally, the yield output is estimated as 48 kg N ha<sup>-1</sup> yr<sup>-1</sup>. Again, we see a different  
597 preference in N outflux partitioning towards large shares in gaseous N fluxes versus small NO<sub>3</sub>  
598 leaching shares and the difference with the results presented in our study are related to the  
599 different input data used for initialization and driving of the model, based on regional statistics  
600 and the use of a biogeochemical model versus emission factor approaches.

601 He et al., (2018) assessed the soil N balance for a time span between 1984 to 2014 based on  
602 the N budget equations (N input – N output) using multiple coefficients from literature in order  
603 to estimate the nitrogen input and output fluxes of six grouped regions in China. The used  
604 datasets were acquired from national Authorities and include cropping land and yields,  
605 synthetic fertilizers, animal heads, soil types etc. The N synthetic fertilizer input is in average  
606 182.4 kg N ha<sup>-1</sup> and the organic fertilizer of 97.3 kg N ha<sup>-1</sup>, N fixation is estimated as 16.8 kg  
607 N ha<sup>-1</sup> and the atmospheric deposition as 22 kg N ha<sup>-1</sup>. Almost half of the total averaged N  
608 output losses, 48.9%, was attributed to crop uptake while the respective gaseous losses were  
609 N<sub>2</sub> 19.9%, volatilized NH<sub>3</sub> 17.3%, N<sub>2</sub>O 1.2% and NO 0.7%. As for the NO<sub>3</sub> leaching share was  
610 5.8% of the total output N fluxes. These reported N outflux proportions comparable well to our  
611 study. The differences in the N uptake data remain and are mainly due to the differences in  
612 the crops and management.

613 As reported in OECD (OECD, 2020) the net averaged nitrogen balance of the area of our study  
614 is 11.6 kg N ha<sup>-1</sup> yr<sup>-1</sup> input to the soil which corresponds very well to the simulated mean  
615 nitrogen balance as an in-flux of 13.8 kg N ha<sup>-1</sup> yr<sup>-1</sup> (IQR 11.9 to 16.0) into the soil.

616 So far, the discussion of the presented N balance and N out fluxes compares well to most of  
617 the available studies reporting N balances while one modelling study report different N outflux  
618 partitioning between gaseous and NO<sub>3</sub> leaching fluxes. For more detailed intercomparison on  
619 the overall quality of our C and N fluxes we aim to compare our results versus various studies  
620 addressing individual components of the C and N balance and associated fluxes.

#### 621 SOC stocks

622 Haas et al., (2022) reported results of a European inventory simulation of soil carbon stocks  
623 and N<sub>2</sub>O emissions using a model ensemble. The study deployed in a baseline simulation  
624 across EU-27 a similar residues management as compared to our study resulting in very stable  
625 carbon stock dynamics over a long period (1950-2100). In this study, the estimated carbon  
626 sequestration of 0.5 (UA mean and median) ± 0.3 tons C ha<sup>-1</sup> yr<sup>-1</sup> is mainly caused by the  
627 inclusion of legume feed crops within the crop rotation leading to increased litter production  
628 and C input into the soil (Barneze et al., 2020; Fuchs et al., 2020; K. Petersen et al., 2021).  
629 Haas et al., (2022) reported a management scenario with 100% of crop litter remaining on the  
630 field leading to averaged C-sequestration rates of over 1 ton C ha<sup>-1</sup> yr<sup>-1</sup> across EU-27. As the  
631 residues management in this study is between the baseline and buried scenario of Haas et al.,  
632 (2022), our results compare well to results reported in this study.

633 Other modelling studies such as (Lugato et al., 2014) reported C sequestration rates for the  
634 conversion of cropland into grassland ranging between 0.4 and 0.8 tons C ha<sup>-1</sup> yr<sup>-1</sup>. Lugato et  
635 al., (2014) reported averaged SOC change rates for a cereal straw incorporation scenario for  
636 EU-27 of 0.1 tons C ha<sup>-1</sup> yr<sup>-1</sup> (estimates from 2000 to 2020).

637 The SOC dynamics reported in this study show a stable carbon dynamic in the soil within the  
638 simulation time span (2009 - 2014) with only three years of model spin-up. The initialization of  
639 the various carbon pools with the SOC data from the soil database is balanced by the average  
640 litter production of the deployed crop rotations. The SOC increase in 2015 and 2016 is due to  
641 climatic conditions and higher litter inputs simulated by the model.

642

## 643 N<sub>2</sub>O emissions

644 This study reported estimates of N<sub>2</sub>O emissions of  $2.6 \pm 0.8$  kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> (IQR from 2.1  
645 to 3.1) for a mixed crop / legume feed crop rotation, which were well above the estimates  
646 resulting from IPCC Tier I direct emission factors, IPCC would lead to 1.6 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup>  
647 when applying 30pprox.. 160 kg N ha<sup>-1</sup> yr<sup>-1</sup>. The higher N<sub>2</sub>O emission strength of the modelling  
648 is likely to result from emission peaks after irrigation due to low anaerobicity (Grosz et al.,  
649 2023; Janz et al., 2022). Cayuela et al., (2017) conducted a meta-analysis of the direct N<sub>2</sub>O  
650 emissions for a number of cropping systems for the Mediterranean climate where the emission  
651 factors (Efs) were altered under different fertilization and irrigation conditions. Higher  
652 fertilization rates led to higher Efs (0.82% less than the 1% of IPCC). Additionally, irrigated and  
653 intensively cultivated crops had higher Efs than rainfed (up to 0.91% dependent on the  
654 irrigation method). The relatively high EF of maize in this study could be possibly attributed to  
655 the irrigation without the application of water-saving methods and the on average higher N  
656 application rates .

657 The LandscapeDNDC validation study of Molina-Herrera et al., (2016) reported for the Italian  
658 site Borgo Cioffi (Mediterranean climate, Ranucci et al., (2011) annual N<sub>2</sub>O emissions of 2.49  
659 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> while two sites in southern France showed annual N<sub>2</sub>O emissions from 0.52  
660 to 3.34 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup>. N<sub>2</sub>O emission estimates of our study were higher than results  
661 reported by Haas et al., (2022) using a multi model ensemble estimating average soil N<sub>2</sub>O  
662 emissions from European (EU-27) cropping systems for the period 1980–1999 of  $1.46 \pm 1.30$   
663 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> under conventional (*Baseline*) management and comparable average N  
664 input. Klatt et al., (2015a) reported for an inventory (Saxony, Germany) mean N<sub>2</sub>O emission  
665 of  $1.43 \pm 1.25$  kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup>..

666 Overall, the reported N<sub>2</sub>O flux component of our study compares well to the findings  
667 reported in literature. As criticized by Grosz et al. (2023), many studies only focus on the  
668 performance of the models in simulating N<sub>2</sub>O emissions and the models were even  
669 calibrated for this purpose. Without reporting all the other N fluxes from the models, this

670 focusing and calibration for only one quantity can easily lead to inaccuracies for other  
671 components of the N cycle as they may not be checked for consistency anymore.

672 Janz et al., (2022)Janz et al., (2022)

673 Nitrate leaching

674 This study reported average NO<sub>3</sub> leaching fluxes (only nitrate leaching into surface waters) of  
675  $14.1 \pm 4.5$  kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>. Reported nitrate leaching observations for the region or Greece  
676 could not be found in literatureestimated the NO<sub>3</sub> leaching with the use of four different models  
677 with varying values from 5 to 40 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup> for the area of our study. These high values  
678 could be explained by the fact that it corresponds both to groundwater and runoff. Molina-  
679 Herrera et al., (2016) reported for the LandscapeDNDC validation study cropland nitrate  
680 leaching fluxes of approx. 7 to 88 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>. In addition, in the research of Molina-  
681 Herrera et al., (2017) the described NO<sub>3</sub> leaching results varied from 13 to 8 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>  
682 <sup>1</sup> showing higher values in regards to the precipitation and fertigation. The most comparable  
683 site Borgo Cioffi resulted in a comparable annual NO<sub>3</sub> leaching flux of 18.62 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>  
684 <sup>1</sup>.

685 Klatt et al., (2015b) reported in an uncertainty assessment for a regional inventory (Saxony,  
686 Germany) leaching rates of  $29.32 \pm 9.97$  kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup> for a wheat-barley-rapeseed  
687 rotation simulated by the LandscapeDNDC model. The agricultural system and management  
688 regime is comparable; higher NO<sub>3</sub> leaching rates were most likely due to high N fertilization  
689 rates in combination with higher annual precipitation in the region leading to more intense  
690 percolation and therefore to stronger leaching of available NO<sub>3</sub> while in our study the  
691 fertilization regime was more lean such that soil nutrient competition was higher and available  
692 nitrate was more likely to be immobilized by plant uptake. Myrriotis et al., (2019) reported in a  
693 similar assessment NO<sub>3</sub> leaching factor (LF) mean for their region of 14% ( $\pm 7$  %), in  
694 comparison we report mean NO<sub>3</sub> leaching factor of 7%.

695

696 NO emissions

697 In the current study, the model estimated NO emissions were in average  $3.2 \pm 1.5$  kg NO-N  
698  $\text{ha}^{-1} \text{yr}^{-1}$ . Butterbach-Bahl et al., (2009) performed the very first European inventory of soil NO  
699 emissions using a modified version of DNDC reporting low NO emission rates mostly below 2  
700 kg NO-N  $\text{ha}^{-1} \text{yr}^{-1}$ . Molina-Herrera et al., (2017) recently reported a full NO emission inventory  
701 for the State of Saxony Germany compiling annual NO emissions from agricultural soils  
702 ranging from 0.19 to 6.7 kg NO-N  $\text{ha}^{-1} \text{yr}^{-1}$  simulated by LandscapeDNDC. The study reported  
703 the model performance on simulating soil NO emissions on more than 20 different sites. The  
704 study of Schroeck et al., (2019) reported for a regional inventory of arable soils in Austria  
705 simulated by LandscapeDNDC annual NO emissions of 1.0–1.5 kg NO-N  $\text{ha}^{-1}$  (for the year  
706 2000), while empirical approaches such as Stehfest and Bouwman, (2006) estimated emission  
707 of similar magnitude. Zhang et al., (2015) reported in a model inter-comparison and validation  
708 study of NO and N<sub>2</sub>O fluxes including three ecosystem models, consistent simulation results  
709 for the LandscapeDNDC model with NO emission strengths of cropland soils were between 1  
710 and 3 kg NO-N  $\text{ha}^{-1} \text{yr}^{-1}$  across the sites.

711

712 NH<sub>3</sub> emissions

713 Schroeck et al., (2019) stated that validation studies of NH<sub>3</sub> volatilization for any  
714 biogeochemical model were very rarely reported in literature, mainly due to the complexity and  
715 a lack of flux observations at spatial and temporal high resolution.

716 In our study we estimate soil NH<sub>3</sub> emissions of  $34.0 \pm 6.7$  kg NH<sub>3</sub>-N  $\text{ha}^{-1} \text{yr}^{-1}$ . High NH<sub>3</sub>  
717 volatilization and emission rates can be explained by the predominating neutral to basal soils  
718 conditions (pH values of 7 and above) in the study region favouring the Henry NH<sub>4</sub>/NH<sub>3</sub>  
719 equilibrium towards higher NH<sub>3</sub> gases enabling ammonia to diffuse out of the soil into the free  
720 atmosphere.

721 The IPCC emission factor (EF) method for NH<sub>3</sub> volatilization reports estimates of 20% of N  
722 input into the soil to be volatilized as NH<sub>3</sub>. For our study, IPCC methodology for NH<sub>3</sub> would  
723 lead to 32 kg NH<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, which is well in line with the simulated result.

724 Sidiropoulos and Tsilingiridis, (2009) estimated a national livestock originated NH<sub>3</sub> emission  
725 corresponding to approx. 22 kg ha<sup>-1</sup> yr<sup>-1</sup> for the region of Thessaly.

726 There is a number of national NH<sub>3</sub> inventories which could be considered detailed and well-  
727 studied like the ones in Denmark, Netherlands, Europe, UK and US. In Denmark, (Geels et al.,  
728 2012) used the DAMOS model to estimate the Danish NH<sub>3</sub> emissions (crop, grass and manure  
729 manipulation) where the values ranged in the 5 regions under study from a very small quantity  
730 to 17.4 kg NH<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>.

731 As discussed by Sutton et al., (2013) the majority of the NH<sub>3</sub> emissions come as a result of the  
732 agricultural production and are considerably impacted by climate influence. In the case of NH<sub>3</sub>  
733 volatilization, it could almost double every 5°C temperature given certain complex  
734 thermodynamics dissociation and solubility, whilst soil NH<sub>3</sub> emission is influenced by the  
735 available water quantity allowing the NH<sub>x</sub> dissolution and use by microbial organisms, which is  
736 afterwards leading to decomposition.

737

738

### 739 4.3 Uncertainty Analysis and Quantification

740 Santabárbara, (2019) used the MCMC algorithm to estimate the joint parameter distribution of  
741 the fundamental bio-geochemical process parameters in LandscapeDNDC when simulation  
742 soil C and N fluxes. Propagating these joint parameter distributions through the model (by  
743 sampling 500 joint parameter distributions and performing inventory simulations with each  
744 parameter set with the model) for estimating the regional C and N fluxes was leading to various  
745 distributions for any model result on the regional scale. Statistical analysis calculating mean,  
746 median as well as the interquartile range (Q25 to Q75) determines best estimates and the  
747 uncertainty range of any model output on the regional scale, demonstrating the superiority of

748 the method for assessing any ecosystem response by modelling instead of reporting single  
749 results. This is a novel approach, that to our knowledge has not been reported before in  
750 literature for the full carbon and nitrogen balance and neither been applied to regional  
751 simulations by any process-based model.

752 In this study, the estimated UA mean and median of the carbon sequestration of  $0.5 \pm 0.3$  tons  
753 C ha<sup>-1</sup> yr<sup>-1</sup> is associated with an uncertainty range from 0.4 to 0.7 tons C ha<sup>-1</sup> yr<sup>-1</sup> which  
754 compares well to the spatial uncertainty of C-sequestration in the study of Haas et al., (2022).  
755 The approach used in this study enabled to assess the carbon and nitrogen balance of the  
756 Lehuger et al., (2009b) used the Bayesian calibration method for the enhancement of the  
757 CERES-EGC model parameterization (reduction of the apriori parameter distribution) as well  
758 as quantification of the uncertainty of the simulated N<sub>2</sub>O emissions in different sites. The  
759 estimated fluxes of the different sites resulted in a range between 0.088 to 3.672 kg N<sub>2</sub>O-N ha<sup>-1</sup>  
760 yr<sup>-1</sup> with values for the q05 quantile of 0.066 to 0.115 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> and for the Q95  
761 quantile from 1.676 to 5.874 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> with an averaged value of 1.04 kg N<sub>2</sub>O-N ha<sup>-1</sup>  
762 yr<sup>-1</sup> which is lower than the result of the current study but still in the same order of magnitude.  
763 Klatt et al., (2015b) quantified a parameter-induced uncertainty analysis on the regional scale  
764 applying the same process model for simulating N<sub>2</sub>O emission and NO<sub>3</sub> leaching inventories  
765 similar to our study. The region was represented by 4000 polygons of arable land (state of  
766 Saxony, Germany) for crop rotations of barley, wheat and rapeseed while climatic conditions  
767 differ. The results of Klatt et al., (2015b) display a likelihood range of 50% (the IQR range  
768 between Q25 and Q75) for N<sub>2</sub>O emissions from 0.46 to 2.05 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> which is in  
769 good comparison to our results of 2.1 to 3.1 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup>. The average N<sub>2</sub>O emissions  
770 are 1.43 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> comparable to the result of our study (mean: 2.6 and median: 2.5  
771 kg N<sub>2</sub>O-N ha<sup>-1</sup> yr<sup>-1</sup> across approx. 1000 polygons). As for leached NO<sub>3</sub>, Klatt et al., (2015b)  
772 reported leaching rates of mean value: 29 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, (IQR from 24.5 to 36.0), which  
773 is higher compared to the results of our study: Mean: 14.1 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup>, median: 13.6  
774 kg NO<sub>3</sub>-N ha<sup>-1</sup> yr<sup>-1</sup> (IQR from 11 to 17). Despite the difference in climatic and soil conditions,

775 both uncertainty analysis studies reported similar regional estimates and uncertainty ranges  
776 for N<sub>2</sub>O emissions and NO<sub>3</sub> leaching.

777 Butterbach-Bahl et al., (2022) reported the influence of management uncertainties for  
778 compiling national inventories of CH<sub>4</sub> and N<sub>2</sub>O emission from various rice cultivation systems  
779 in Vietnam. The study applied a sampling technique varying model input data within a given  
780 range and analysing the influence on the assessed CH<sub>4</sub> and N<sub>2</sub>O emission strengths. As the  
781 underlying cropland systems were fundamentally different, the assessed uncertainty ranges  
782 were comparable and the study is supporting our approach to focus on reporting uncertainty  
783 ranges rather than single values.

784

## 785 5 Conclusion

786

787 In this research, we presented for the first time a regional inventory of the full carbon and  
788 nitrogen balance including all sub-components of these fluxes simulated by a process-based  
789 model. Additionally, the study has fulfilled the demand to report always the associated  
790 uncertainties for any modelling results being published in literature. This supports the  
791 trustworthiness of the reported results for the C and N balances.

792 Comparing the modelled N balance with a similar approach modelling the full N balance with  
793 all associated fluxes for a catchment in pre-alpine Austria leads to the conclusion, that  
794 especially the partitioning the N outflux into the different N flux components is more inherent  
795 to the LandscapeDNDC model itself used in both studies than induced by the two very different  
796 agricultural and climatical systems. Nevertheless, specific N outfluxes between the two studies  
797 show large differences (e.g. NH<sub>3</sub> volatilization), which is purely caused by model processes  
798 due to different soil PH values. Comparing to a less granular and detailed study of the N  
799 balance for Switzerland gives a first impressions of the differences to be expected in modelling  
800 the arable N balance with various different models. The discussion of such results will become

801 more lively and maybe controversial as soon as more comparable studies using different  
802 models become available.

803 In addition, a full uncertainty analysis is presented based on the Metropolis-Hastings algorithm  
804 where a parameter subset and input data perturbation was sampled and simulated resulting in  
805 various probability density functions (PDF) for each one of the N and C balance fluxes building  
806 a full uncertainty analysis of the modelled results. This helps to build trustworthiness in  
807 modelling assessments and estimates of the balances as well as of the model behaviour.

808 As demanded by the nitrogen modelling community, all of the above constitute the novelty of  
809 the conducted research that could be seen as a prototype to analyse and report N cycling in  
810 agro-ecosystems in the future.

811

## 812 6 Acknowledgements

813 The author Odysseas Sifounakis received a Ph.D. research scholarship from Alexandros S.  
814 Onassis Public Benefit Foundation, Greece, part of which is the research presented in the  
815 current publication.

816

## 817 7 Code/Data availability

818 The LandscapeDNDC model source code is available via Butterbach-Bahl, Klaus; Grote,  
819 Rüdiger; Haas, Edwin; et al. (2021): LandscapeDNDC (v1.30.4). Karlsruhe Institute of  
820 Technology (KIT). DOI: 10.35097/438

821 All publication results (tables and data for figures) will be made available in the supplementary  
822 material associated with this paper.

823

824

825 8 Author contributions

826 Mr. Odysseas Sifounakis has conceived and designed the analysis and collected the data. He,  
827 also, performed the analysis and wrote the paper.

828 Dr. Edwin Haas conducted research and wrote the paper.

829 Prof. Dr. Klaus Butterbach-Bahl substantially contributed to research planning, manuscript  
830 writing and editing and, also, provided funding opportunities.

831 Prof. Dr. Maria P. Papadopoulou substantially contributed to research planning, manuscript  
832 writing and editing, and provided funding opportunities.

833

834 9 Competing interests

835 All authors have reviewed and accepted the submitted version and declare no conflicts of  
836 interest related to this publication.

1201

1202 11 Appendix

1203 11.1 Material and Methods

1204 **Sensitivity Index**

1205 In the first step, the Sensitivity Index algorithm (SI) (Pannell, 1997) was calculated for all  
 1206 process parameters by splitting the parameter ranges into 10 equidistant values from minimum  
 1207 to maximum and by rating SI values:

1208 
$$SI = \frac{CUM_{max} - CUM_{min}}{CUM_{max}}$$

1209 where  $CUM_{max}$  and  $CUM_{min}$  are the maximum and minimum cumulative results of 10  
 1210 simulations. High SI values explain a high sensitivity of the underlying parameter with respect  
 1211 to the model results, whereas low values or even zero indicates low or no sensitivity.

1212

1213 11.2 Results

1214 *Table A 1. Observed yield rates in the region of Thessaly. Cotton yields are the cotton bolls, clover feed is the total*  
 1215 *harvested above ground biomass, for wheat and barley it is the grain yield, maize is accounted grain ear and the*  
 1216 *stems Source ELSTAT.*

Crop Yields [tons dry matter ha <sup>-1</sup> ]						
Crops	2012	2013	2014	2015	2016	Mean
Cotton	2.7	3.6	3.5	3.4	3.3	3.3
Clover	8.6	8.9	8.7	7.9	7.7	8.4
Wheat	3.3	3.3	3.3	3.7	3.6	3.4
Barley	3.2	3.2	3.2	3.5	3.5	3.3
Maize	10.9	12.1	12.3	12.7	12.1	12.0

1217

1218 *Table A 2. Crop rotation scenarios (R1 – R5) for the region of Thessaly where the crop abbreviations corn, wiwh,*  
 1219 *perg, cott and wbar refer to maize, winter wheat, clover (legume feed crops s.a. alfalfa or vetch), cotton and winter*  
 1220 *barley respectively.*

years	R1	R2	R3	R4	R5
2010	corn	wiwh	perg	cott	wbar
2011	wiwh	perg	cott	wbar	corn
2012	perg	cott	wbar	corn	wiwh
2013	cott	wbar	corn	wiwh	perg

2014	wbar	corn	wiwh	perg	cott
2015	corn	wiwh	perg	cott	wbar
2016	wiwh	perg	cott	wbar	corn

1221

1226 *Table A 4 Nitrogen balance (totals) Summary of the Assessment and Uncertainty Analysis of the total Nitrogen*  
 1227 *Balance of cropland cultivation of the region of Thessaly, Greece.*

	Mean	Std	Median	Q25	Q75
	[kt-N yr <sup>-1</sup> ]	[kt-N yr <sup>-1</sup> ]	[kt-N yr <sup>-1</sup> ]	[kt-N yr <sup>-1</sup> ]	[kt-N yr <sup>-1</sup> ]
N-Inputs	76.5	3.2	77.8	73.3	79.1
N-Outputs	71.7	3.2	71.2	69.4	73.7
N-stock-changes	4.8	0.0	6.6	3.9	5.4
Input fluxes					
N deposition	2.0	0.3	2.1	1.9	2.1
Bio. N fixation	16.7	1.6	16.7	15.9	17.5
N in min. fertilizer	28.9	1.7	29.3	27.6	29.8
N in organic fertilizer	28.9	1.3	29.2	27.9	29.8

Output fluxes					
Gaseous emissions <sup>1)</sup>	21.2	3.1	21.1	18.9	23.4
N <sub>2</sub> O	0.9	0.3	0.9	0.7	1.1
NO	1.1	0.5	1.0	0.7	1.4
N <sub>2</sub>	4.9	2.4	4.5	2.9	6.6
NH <sub>3</sub>	14.3	2.6	13.5	12.5	15.6
Aquatic fluxes <sup>2)</sup>					
NO <sub>3</sub> leaching	3.9	1.3	3.8	3.0	4.7

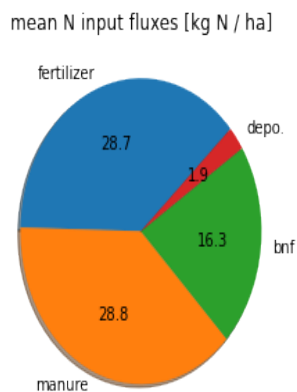

1228 1) Gaseous emissions are the sum of N<sub>2</sub>O, NO, N<sub>2</sub> and NH<sub>3</sub> fluxes; 2) Aquatic flux is nitrate leaching (NO<sub>3</sub>-)

1229

1230 Table A 5. Total crop yields per cultivar and year.

Crop Yields [tons dry matter]						
Crops	2012	2013	2014	2015	2016	Mean
Cotton	303 676.9	374 424.6	359 806.7	322 292.0	285 780.3	329 196.1
Clover	302 753.2	319 401.7	338 134.6	341 938.4	360 693.9	332 584.4
Wheat	477 700.7	461 875.5	395 902.1	430 014.4	450 254.3	443 149.4
Barley	84 520.8	99 091.8	139 402.9	139 990.8	102 454.7	113 092.2
Maize	332 531.6	431 324.6	377 783.9	351 285.4	334 277.7	365 440.6
