Abstract

In the deep -sea, the interactions between benthic fauna and seafloor sediment substrate mainly primarily occurs through bioturbational processes which that can be preserved as traces (i.e., lebensspuren). Lebensspuren are common features of deep-seafloor landscapes and are usually more abundant than the organism that produce them (i.e., tracemakers), rendering them promising proxies to inferfor inferring biodiversity. The density and diversity relationships between lebensspuren and benthic fauna are to the present dayremain unclear and contradicting correlations hypotheses have been proposed suggesting (i.e., negative, positive, or even null correlations). To approach test these variable -correlations hypotheses, in this study lebensspuren and , tracemakers (specific epibenthic fauna that produce these traces), degrading fauna (benthic fauna that can erase lebensspuren), and benthic fauna in general were characterized taxonomically at eight deep-sea stations in the Kuril Kamchatka Trench area; together with two novel categories: tracemakers (specific epibenthic fauna that produce these traces) and degrading fauna (benthic fauna that can erase lebensspuren). No general correlation (over-all study area)

Con formato: Sangría: Primera línea: 1,25 cm

could be observed between diversities of lebensspuren, tracemakers, degrading fauna and fauna. However, a diversity correlation was observed at ~~between~~ specific stations, showing both negative and positive correlations depending on: 1) the number of unknown tracemakers (especially significant for dwelling lebensspuren); and 2) the lebensspuren with multiple origins; and 3) tracemakers that can produce different lebensspuren. Lebensspuren and total faunal density were not correlated. However, lebensspuren density was either positively or negatively correlated with tracemaker densities, depending on the lebensspuren morphotypes. A positive correlation was observed for resting lebensspuren (e.g., ophiuroid impressions, Actinaria circular impressions), while negative correlations were observed for locomotion-feeding lebensspuren (e.g., echinoid trails). In conclusion, lebensspuren diversity may be a good proxy for tracemaker biodiversity when the relationship lebensspuren-tracemaker ~~tandem~~ can be reliable characterized.~~; and l~~ Lebensspuren-density correlations vary depending on the specific lebensspuren residence time, tracemaker density and associated behaviour (rate of movement). Overall, we suggest that lebensspuren density and diversity correlations should be done with tracemaker rather than with general benthic fauna. ~~, but o~~On a global scale abiotic (e.g., hydrodynamics, substrate consistency) and other biotic factors (e.g., microbial degradation) may also play an important role.

Introduction

Neoichnology studies the interactions between animals and substrates (~~i.~~e.g., bioturbation ~~processes~~) in modern environments ~~-~~as well as the biogenic sedimentary resulting from these interactions~~as well as their final products~~, the so-called lebensspuren (German for "life traces"; e.g., faecal casts, trails, mounds, burrows) (Ewing and Davis, 1967; Gage and Tyler, 1991). In the marine realm, ~~-~~lebensspuren analyses~~is~~ are usually image~~s~~ based (e.g., Bell et al., 2013; Miguez-Salas et al., 2023). ~~-~~Lebensspuren are ~~highly precise~~

portraits of the diverse linkages between environmental conditions and the animal responses to them. Thus, neoichnological analyses~~is~~ ~~provide~~offer~~s~~ a useful tool set for deducing~~to infer~~ environmental factors ~~not only in~~in both contemporary and past environments ~~but also deliver evidences to past environments~~ through comparisons between lebensspuren and trace fossils (Buatois and Mángano, 2011). However, neoichnology as a field is not yet as developed as paleoichnology (i.e., trace fossil research), and most quantitative studies are restricted to shallow marine environments and tank experiments (e.g., shoreface, foreshore, marginal marine settings) (La Croix et al., 2022 and references therein). Even though the abyssal zone (i.e., 3500-6500 m deep) represents the largest marine ecosystem and covers approx. 75% of the seafloor (Ramirez-Llodra et al., 2010; Watling et al., 2013), neoichnological analyses are scarce and limited by the ~~, mainly due to the~~ cost of observation and sampling procedures (e.g., Heezen and Hollister, 1971; Przeslawski et al., 2012; Bell et al., 2013; Miguez-Salas et al., 2022). As such~~Thus~~, neoichnological analyses are emerging ~~e~~ as a promising tool for ~~to~~ ~~enhance~~furthering our understanding of deep-sea environments and faunal-sediment interactions.

Quantitative marine ecological research comprises two main components - d~~D~~iversity and density analyses ~~are two main components of quantitative marine ecological research~~ (Halpern and Warner, 2002). Deep-sea neoichnological studies have addressed diversity and density characterizations by considering all identified lebensspuren as morphotypes ~~as “species”~~ (Przeslawski et al., 2012; Bell et al., 2013). However, tracemaker (i.e., the benthic organisms that produce ~~the observed~~ lebensspuren) diversity and density have been approached from a generalist perspective as megafauna, epifauna, or lebensspuren-forming epifauna (Young et al., 1985; Dundas and Przeslawski, 2009; Przeslawski et al., 2012; Bell et al., 2013).

Con formato: Sangría: Primera línea: 1,25 cm

Early deep-sea neoichnological studies ~~suggested~~ suggested a correlation between ~~that~~ lebensspuren ~~diversity is proportional to~~and faunal diversity (Kitchell et al., 1978, Young et al., 1985). However, more recent studies ~~have shown~~show ~~-~~no significant correlation between epifaunal and lebensspuren richness (Przeslawski et al., 2012)~~ and that lebensspuren diversity was not similar to that of epifaunal lebensspuren-forming diversity (Bell et al., 2013)~~. Bell et al. (2013) stated that "improvements in imaging technology allow more refined classification of lebensspuren and ~~species~~organisms, which may affect the strength of the correlation between faunal and lebensspuren diversity, compared with the more direct proportionality of faunal and lebensspuren diversity demonstrated in earlier studies". Thus, in deep-sea research, diversity comparisons based on more precise taxonomic tracemaker identification and differentiation are a pending task, promising a deeper understanding of the dependencies between fauna and lebensspuren variability.

~~In the case of lebensspuren density, early~~Early studies ~~revealed~~ found an inverse relationship ~~with~~ between lebensspuren and faunal density (Kitchell et al., 1978, Young et al., 1985; Gerino et al., 1995). These studies suggested that this relationship is related to the fact that lebensspuren formed in low biomass regions have the capacity to persist for a long time (high residence time), ultimately leading to a steady increase of the lebensspuren density through accumulation. Nevertheless, recent data seemed to conflict with this initial assumption. Przeslawski et al. (2012) observed no discernible correlation between ~~that~~ lebensspuren and epifaunal abundance~~ ~~. Contrastingly, ~~do not have any relationship; and, contrastingly,~~ Bell et al. (2013) ~~found~~ reported a strong positive ~~relationship~~ correlation between lebensspuren and faunal densities (see Fig. 10 in Bell et al., 2013). The results from ~~These newer results~~Bell et al. (2013) suggest ~~show~~ that megafaunal activity ~~may not be the only~~might not be the only factor influencing the preservation or destruction of l~~ significant factor for l~~ebensspuren~~ destruction or~~

preservation. Small scale biotic factors (e.g., microbial degradation), as well as abiotic factors (e.g., hydrodynamic regimes, sedimentations rates, sediment composition) may potentially limit_ lebensspuren residence time and density at different across different spatial scales in the deep -sea (Wheatcroft et al., 1989; Smith et al., 2005; Miguez-Salas et al., 2020). In summary, earlier investigations and their contradicting results strong variability in the few previous studies and conflicting conclusions drawn from these highlight that neoichnology and its fundamental concepts are still in their infancy early stages and needwarrant further explorationinvestigation.

Despite the presence of manyprevalence of lebensspuren on the deep seafloor (Heezen and Hollister, 1971), only a very few organisms are recognized in the process of forming these features. Thus, understanding the density-diversity relationship between lebensspuren and benthic megafauna may help decipher variability of the former indirectly (i.e., without having seen the organisms). The research presented here aims to compare diversityies indices and densities of lebensspuren, specific tracemakers (specific organism that produce them), degrading fauna (benthic fauna that can erase lebensspuren), and megabenthic fauna from the Northwest Pacific Abyssal Plain, near the in the direct vicinity of the Kuril Kamchatka Trench (KKT) (Fig. 1). By conducting a detailed classification of both lebensspuren and tracemakers, this research wants to go one step further with the main objective to test how previous diversity and density relationships hypotheses about the relationship vary from previous results where between the variability of lebensspuren was compared with and fauna diversity in a much coarser taxonomic resolution. –Thise geographic region has been is well studiedstudied extensively, with research dating back from eleven as it has a long research history that began with eleven expeditions onboard aboard theof R/V *Vityaz* (Russian expeditions; 1949, 1953 and 1966) to more recent research efforts aboard the R/V *Sonne*. and was

~~m/s, and further reduced to 0.3 m/s at 200 meters above ground.~~ the winch lowering the OFOS was stopped and the ship resumed steaming at 0.5 knots in a direction chosen~~As soon as visual contact with the bottom was established, the winch was stopped. The ship started moving with 0.5 knots above ground in the appropriate direction, which was chosen~~ depending on the water current and wind situation. Then, the winch operator manually kept the OFOS at an appropriate distance from the seafloor to observe the seafloor benthos. Two laser pointers ~~having~~ with ~~a distance of 10~~10 cm between ~~each other were~~them were used as a scale. The first four deployments were aborted due to technical problems, affecting stations 1–3 (Table 1). Thus, limited video footage was obtained. Moreover, station 7 ~~has~~lacked ~~no~~ HD video and was therefore not considered for ~~(i.e., this station is not considered for~~ the current analysis~~)~~. All technical ~~work~~aspects, including pre-deployment preparation and post-deployment maintenance (i.e., ~~before and caretaking after (~~including video download) were managed~~the deployment was conducted~~ by the scientific-technical service (“WTD”, Wissenschaftlich-Technischer Dienst, Jörg Leptien, Reederei).

~~At each station, S~~Still images were extracted from the OFOS videos ~~were extracted~~ at a frequency of on~~from the OFOS videos at a rate of on~~e frame per five seconds (Miguez-Salas and Riehl, 2023a). These still images were then ~~subsequently further~~ sub-sampled to delete frames that were out of focus to minimize frame overlap. Out of focus frames were defined as frames showing the OFOS moving up and down due to ocean swell. ~~— as the rolling of the ship in the ocean swell resulted in an up and down movement of the OFOS — and to reduce overlap between frames. Then, 50~~Fifty frames per station (400 still images in total), covering a seafloor area of 878 m^2 (109 m^2 per station approx.), were randomly selected ~~frames per station were studied (400 still images in total)~~and uploaded to the BIIGLE 2.0 software for later annotation and measurements

(Langenkämper et al., 2017). , covering a seafloor area of 878 m^2 (109 m^2 per station approx.). These still images were uploaded to the BIIGLE 2.0 software for later annotation and measurements (Langenkämper et al., 2017). SpecificSpecific frames were treated with Fiji software (Schindelin et al., 2012) to enhance the visibility (CLAHE tool) of certain lebensspuren features (Miguez-Salas et al., 2019).

Lebensspuren classification and tracemaker identification

Lebensspuren morphotypes were categorized in terms of inferred tracemaker behaviour during the constructiontheir formation, their morphology, and the taxonomic origin of the tracemaker–staxonomic origin. The behavioural classification was adapted from Seilacher's (1954) categories for marine lebensspuren: i. Resting (imprints of stationary animals); ii. Locomotion-feeding (sediment displaced by the movement of deposit feeders and surface sediment disturbances formed as organisms are foraging); iii. Wasting (e.g., faecal casts, pellets); and iv. Dwelling (e.g., mounds and burrows). The morphological classification followed previous morphological names (e.g., Ewing and Davis, 1967; Young et al., 1985; Dundas and Przeslawski, 2009; Przeslawski et al., 2012; Althaus et al., 2015), where such exist. Morphological features measured included in the classification were length, width, and diameter. Lebensspuren with unclear morphology and origin (e.g., degraded faecal casts, trails with diffuse outlines) were not considered in thisexcluded from analyses study. Additionallylso, lebensspuren and fauna smaller than 1 cm (macrofauna and smaller) were also excluded from analyses as the resolution of the still images is below high-definition (<1280x720 pixels). lebensspuren and fauna smaller than 1 cm (macrofauna and smaller) have not been considered in this study. Hence, this study focuses only ses on megafauna (i.e., fauna > 1 cm), which is implied whenever throughout this study when fauna is mentioned in this study from hereon.this point forward.

This study aimed for the~~The~~ species rank, which is fundmanteal, gold standard~~–~~ ~~the basic, gold-standard~~ taxonomic level to which ecological studies generally aspire. ~~–~~ ~~was aimed for in the discrimination of taxa.~~ However, names of described species could not be attached to these taxa in the majority of our image-based observations for reasons of limitation in the image quality and the general difficulty to observe diagnostic characters in *in-situ* photographs. ~~So~~As such, o~~O~~pen nomenclature has been used instead ~~for megafauna taxonomic identification~~ , following the recommendations for image-based identifications ~~proposed~~ laid out by Horton et al. (2021). ~~All differentiated morphotypes are henceforward referred to as “species” for simplicity. Then,~~ F~~f~~auna has been grouped into different categories for comparisons with the diversity and density of lebensspuren: 1) tracemakers (fauna that has been clearly recognized as maker of a trace); 2) degrading fauna (fauna that can affect lebensspuren density negatively by eroding the seafloor); and 3) benthic fauna (all fauna identified in the still images).

Statistical analysis

~~For statistical analysis, all identified lebensspuren and fauna morphotype were treated as “species”.~~ Diversity indices (Shannon–Wiener H′ ($\log_e$) and Simpson’s D) and evenness (J′) were calculated for ~~the~~ four groups: lebensspuren, tracemaker fauna, degrading fauna, and fauna. As the data from all groups show non-parametric distribution ~~throughout~~ for all stations, diversity variability among stations was tested using Wilcoxon signed-rank test (considering all groups and all indices). ~~Then, the~~The Spearman rank correlation was used to test the relationships between the diversity indices of all groups.

~~For density correlations (Spearman rank correlation), since~~ As the number of frames was the same (i.e., same observation area), ~~the analyses~~density correlations analyses were ~~conducted considering the~~performed by separately considering the total density per ~~station of all groups individually~~for each group at every station. Additionally,

lebensspuren and tracemakers densities were further subdivided into three groups:~~into~~ wasting, resting and locomotion-feeding. ~~(D~~dwelling was not considered ~~because~~ as the tracemakers of most dwelling lebensspuren are unknown~~)~~.

Multivariate analyses was conducted t~~To~~ investigate potential differences within the ~~four groups~~ (lebensspuren, tracemakers, degrading fauna, and total benthic fauna groups.~~) between stations, multivariate analysis was conducted~~. First, a square root transformation was carried out to give less weight to the more abundant ~~species~~ taxa of organisms and lebensspuren morphotypes. Then, differences in the composition of the four groups between stations were assessed using hierarchical cluster analysis and displayed as non-metric multidimensional scaling plots (n-MDS). Both plots were constructed using the Bray–Curtis similarity index. All statistical procedures were conducted using PAST v. 4.12 (Hammer et al., 2001).

Results

A total of 9,426 lebensspuren were identified and classified from 400 still images, corresponding to 23 morphotypes associated with dwelling, wasting, resting, and locomotion-feeding behaviours (Fig. 2; Table 2) (for raw dataset report at each station consult: Miguez-Salas and Riehl, 2023b). The fauna comprised a total of 4,009 individual animals that were classified into 93 different ~~species(terminal)~~ taxa, of which 66 were classified as degrading fauna and 43 as tracemakers (with 790 and 676 individuals respectively) (Table 3;~~-~~ Miguez-Salas and Riehl, 2023b~~Supplementary file 1~~). Linking dwelling lebensspuren with tracemakers ~~was mostly impossible~~proved to be challenging, with the ~~exception except for of~~exception of rare and ambiguous cases where vermiform organisms, most likely polychaetes, partially emerged from paired burrows (Fig. 2P). Tracemaker identification was possible in ~~the majority of~~most of the cases for wasting lebensspuren.~~;~~ ~~however,~~ I~~i~~t is common ~~that different~~for different tracemakers to produce

Con formato: Sangría: Primera línea: 1,25 cm

the same lebensspuren morphotypes and it is also common for one tracemaker (taxon) to produce ~~that~~ several lebensspuren morphotypes ~~of lebensspuren are produced by one tracemaker species taxon~~ (see Table 2). However, in the case of cf. *Elpidia* — the most abundant tracemaker of station 4 (see Miguez-Salas and Riehl, 2023b~~Supplementary file 1~~) — the complete characterization of its associated rounded faecal cast (smaller than 1 cm) was impossible due to image resolution limitations. Tracemaker identification of locomotion-feeding lebensspuren was mostly possible except for mounded trails which have been produced by endobenthic organisms. However, as for wasting lebensspuren, also in this case different tracemakers can be responsible for similar trails (see Table 2). Tracemaker identification of resting lebensspuren ~~has been possible in most cases.~~ w~~W~~as possible for most of the cases.

The Wilcoxon signed-rank test revealed that ~~for all groups~~ the median diversity was significantly different between stations for all groups and was, ~~being lower at~~lowest at stations 9 and 11 (Fig. 3). Moreover, faunal diversity showed a standard deviation three orders smaller than the values reported for lebensspuren, tracemakers, and degrading fauna; showing that faunal diversity was more consistent among sites that the other diversity indices. Lebensspuren diversity indices (Shannon–Wiener, Simpson's and Evenness) of the over-all KKT area (considering all the eight stations together) showed no correlation with comparable diversity indices from the other three groups ~~the other three groups~~ (tracemakers, degrading fauna, and benthic fauna). The only strong diversity correlation resulting from the Spearman rank analysis was between tracemakers and degrading fauna ($R^2 > 0.88$, $p < 0.01$).

The density correlation matrix revealed no significant correlation between the fauna and the other groups (see Fig. 4). The degrading fauna showed a positive correlation with tracemaker and waste ~~wasting~~ tracemakers densities. Also, tracemakers and waste

Con formato: Sangría: Primera línea: 1,25 cm

Con formato: Fuente: (Predeterminada) Times New Roman, 12 pto, Sin Cursiva, Inglés (Reino Unido)

~~wasting ~~tracemakers densities are positively correlated (Fig. 4). A~~In case of the lebensspuren data, a ~~positive density correlation was obtained between lebensspuren and wasting lebensspuren as well as resting lebensspuren and resting tracemakers. ~~while a~~A negative correlation was observed for locomotion-feeding lebensspuren and their tracemakers (Fig. 4).

~~Inter-station similarity of l~~Lebensspuren assemblages~~ composition ~~ were~~as~~ generally similar among stations ~~high ~~(Fig. 5 A), ranging from 75–82% similarity in the cluster analysis. The n-MDS showed that lebensspuren assemblages from stations 5, 6, 8, and 10 are different from the trench (stations 3 and 4) and the southern stations (stations 9 and 11) (Fig. 6 A). The southern stations were less diverse, similar (82% similarity; Fig. 5A) and dominated by rounded faecal casts produced by *Scotoplanes* spp. The trench stations were characterised by diverse and slightly less similar assemblages (75% of similarity) dominated by dwelling lebensspuren (e.g., paired, lined or cluster burrows), knotted faecal casts (*Peniagone* spp.), ophiuroid impressions (Ophiuroidea), circular impressions (Actinaria) and ~~thick ~~M-ridged trails (Aste~~o~~roidea and *Echinocrepsis* spp.). Stations 5, 6, 8, and 10 showed diverse lebensspuren assemblages dominated by smooth (cf. *Benthodytes*, *Psychropotidae*) and coiled~~-~~ curly faecal casts (*Psychropotidae*), rosette-shaped traces and ~~thick ~~flat trails (Astero~~r~~idea, cf. *Benthodytes*, *Psychropotidae*) (Fig. 6 A).

The hierarchical cluster diagram for tracemakers, degrading fauna and fauna showed less similarity between stations than it was the case for lebensspuren, especially for tracemakers and degrading fauna (values ranging from 20–55% similarity in the cluster analysis) (Fig. 5 B–D). However, the trench stations (Stations 3 and 4) and the southern stations (Stations 9 and 11) seemed to have similar compositions respectively. The low inter-station similarity of tracemakers, degrading fauna and fauna assemblages

Con formato: Sangría: Primera línea: 1,25 cm

was also reflected in the n-MDS plots where the spacing between stations was considerably higher than in the lebensspuren plot (Fig. 6 B–D).

Discussion

The ~~obtained~~ results from the KKT area reveal that the relationship between lebensspuren, tracemakers, and fauna is ~~may be~~ more complicated than initially ~~previously~~ hypothesized (Kitchell et al., 1978; Young et al., 1985) and may follow the complex puzzle exposed in recent research (Przeslawski et al., 2012)~~–~~. ~~On the one hand, a~~While a general null diversity correlation has been observed between lebensspuren, tracemakers and fauna, ~~.~~ ~~On the other hand,~~ density correlations seem to be morphospecific (e.g., depending on the lebensspuren-associated behaviour). But to what extent do the obtained results contradict or corroborate previous results and what are the limitations when addressing the diversity and density of lebensspuren?

Fauna, tracemakers and lebensspuren diversity: a complex relationship

Previous comparisons between lebensspuren and faunal diversity have given rise to different contrasting hypotheses. Though p~~P~~ioneering research showed positive correlations (e.g., Kitchell et al., 1978, Young et al., 1985), ~~.~~ l~~L~~ater ~~on, several~~ studies showed no correlation at all (e.g., Tilot, 1995; Turnewitsch et al., 2000; Przeslawski et al., 2012). ~~All~~ T~~t~~hese studies ~~have in common~~share a common approach in which ~~that~~ the diversity comparisons ~~was~~ were ~~addressed~~ conducted from a ~~general~~ broad perspective, especially for tracemaker organisms. Comparisons were ~~done either~~conducted using ~~considering~~ megafaunal ~~species~~ taxa (Young et al., 1985), epifaunal ~~species~~ taxa (Przeslawski et al., 2012) or certain taxonomic groups of organisms (e.g., fish, holothurians, crinoids; Kitchell et al., 1978). Only Bell et al. (2013) approached the comparison between lebensspuren and fauna in greater detail by ~~-~~considering groups of lebensspuren-forming epifauna, and using indices to quantify lebensspuren diversity (e.g., Simpson, Shannon-Wiener). Their analyses ~~, discovering~~revealed that "l~~L~~ebensspuren diversity was generally high and not similar to that of lebensspuren-forming faunal diversity" (Bell et al. 2013). However, the links between specific tracemakers and their lebensspuren and the subsequent tracemaker diversity indexes are missing in Bell et al.'s (2013) study. In this study we ~~have tried to~~attempt to close this knowledge gap by ~~comparing~~ conducting a comprehensive ~~comparision~~comparison of ~~the~~ lebensspuren diversity. We examine ~~with~~ not only the faunal diversity but also encompass ~~the~~ tracemaker and degrading fauna (i.e., fauna that may alter the lebensspuren assemblage by erosion/degradation). Our results show that lebensspuren diversity (Simpson, Shannon-Wiener, and Evenness) is not related to fauna, tracemaker or degrading fauna diversity. ~~This finding~~These findings seem ~~s~~ to corroborate ~~the latest~~ results of a non-existent correlation (Przeslawski et al., 2012; Bell et al., 2013). However, can ~~, but can~~ this lack of correlation be expected in all deep-se~~a~~e settings?

~~Before answering this question,~~ This question cannot be answered without considering the limitations of quantifying deep-sea lebensspuren diversity, which is riddled with problems. These problems include ~~should be considered. There are several problems when it comes to quantifying lebensspuren diversity (e.g.,~~ image resolution, camera systems, unknown lebensspuren, ~~unknown tracemakers,~~ observation scale, trace degradation~~,)~~, but the most important is linked to their genesis. In other words, the same lebensspuren morphotype~~s~~ (or indistinguishable lebensspuren) can be produced by different tracemakers and one tracemaker can produce different lebensspuren (see Table 2). For example, in ~~case of this~~this study, several different holothurians (e.g., cf. *Pseudostichopus, Psychropotes, Synallactidae, Benthodytes*) could have produced the smooth faecal casts. Contrastingly, ~~could have been produced by different holothurians~~

~~(e.g., cf. *Pseudostichopus, Psychropotes, Synallactidae, Benthodytes*) and~~ *Psychropotes* can be linked to the production of coiled-curly and smooth faecal casts as well as ~~thick~~ flat trails (Fig. 2G). Thus, when comparing their diversity, ~~the basis that each~~ it should be taken into account that lebensspuren morphotypes may not be related to one specific ~~species~~ taxon and *vice versa*~~, should be considered~~. However, ~~the fact~~while ~~that in our study~~ general lebensspuren diversity in the present study did not correlate with tracemaker diversity, this does not mean ~~that this will be the case in all deep-sea settings~~ that the same applies to all deep-sea settings. It is possible that a more precise characterization of ~~if~~ ~~the~~the tracemaker-lebensspuren relationship ~~tandem can be characterised more precisely~~ or if tracemakers produce ~~just one~~ specific lebensspuren morphotypes may reveal a different ~~corelation~~correlation in other settings. ~~.~~

~~In our study area,~~We observed different correlations between tracemakers and lebensspuren ~~could be observed~~ when ~~comparin~~comparing~~g the~~ diversity among specific stations. For example, ~~when restricting the~~ comparison ~~to~~ of the southern stations (stations 9 and 11~~), a correlation was observed between~~) using Simpson and Shannon-Wiener indexes ~~of~~ showed a correlation between tracemakers and lebensspuren diversities (Fig. 3). ~~This was due to the fact~~This can be attributed to the traces dominating the ~~that the~~ assemblage ~~is dominated by traces~~ for which we have ~~been able to identify~~ ~~the~~successfully identified tracemakers (e.g., rounded faecal casts of *Scotoplanes*). On the contrary, ~~when focussing on the trench~~comparison of the trench stations ~~(stations~~ 3 and 4 using Simpson and Shannon-Wiener indexes revealed~~),~~ a negative correlation ~~could be observed~~ between ~~Simpson and Shannon-Wiener indexes~~ of tracemaker and lebensspuren diversities (Fig. 3). This ~~could~~ can be attributed to the relatively large gap in our data regarding the origin of most traces of the lebensspuren assemblage. ~~(S~~Stations 3 and 4 have a high abundance of dwelling lebensspuren (see Table 3), ~~;~~ single burrows, mounds,

Con formato: Sangría: Primera línea: 1,25 cm

cluster burrows for which tracemakers are unknown~~)~~ and dominant tracemakers (*Elpidia*) whose traces cannot be correctly quantified due to image resolution limitations (small rounded faecal casts). ~~-~~Also, the existence of unknown lebensspuren and tracemakers ~~will contribute to the~~contributes to the correlation variability.

The enhancement of image resolution and the increase of deep-seafloor area covered by still image surveys may allow the~~o~~ improvement of lebensspuren classification and their tracemaker identification. There is ~~a lot of room for~~ample room for improvement, especially with regard to locomotion and feeding lebensspuren. High definition still images will allow researchers to characterize ~~, for example,~~ small morphological features of trails (e.g., podia marks from asteroids, echinoid spine impressions), allowing for a much more detailed classification than ~~what~~ could be achieved within ~~for~~ this study. The use of artificial intelligence, ~~which seems to be a very~~a seemingly promising tool in the assistance of benthic fauna recognition in imagery analyses, appear to have~~s a~~ restricted applicability in the characterization of lebensspuren. This is because lebensspuren ~~since they~~ are constructed with sediment ~~which usually have~~that has the same texture as the seafloor (i.e., background colour). In the case of dwelling lebensspuren diversity, comparison is significantly more complicated. ~~because t~~Trace morphology is largely hidden below the seafloor surface, reducing the ~~possibility~~ ability to differentiate between ~~different~~ various burrow morphologies. Additionally, ~~while~~ tracemakers are ~~mostly unknown~~largely unidentified due to ~~a~~ their predominantly endobenthic lifestyle (e.g., Brandt et al., 2023). ~~Furthermore~~Finally, it is worth noting that burrows and other dwelling lebensspuren ~~also could potentially~~may have multiple potential origins ~~(e.g., a paired burrow can be produced by multiple species of polychaetes or bivalves)~~.

The fact that the same lebensspuren morphotypes can be produced by different tracemakers and one tracemakers can produce different lebensspuren will affect the establishment of a positive or negative diversity correlation. Also, the existence of unknown tracemakers will contribute to the correlation variability. However, as tThe obtained resultsOur results show that in specific stations where the, when the assemblage is dominated by traces with identifiable tracemakers, lebensspuren analysis emerges as aappears to be a- promising tool to for predicting tracemaker diversity. Although these results are promising, it is evident that much more research is needed, especially Despite of these optimistic results, it is fair to say that much more research is needed — with high definition surveys (e.g., videos, images) —to close existent existing knowledge gaps in the relationship between lebensspuren-and tracemaker tandem. Moreover, we emphasize that when using lebensspuren as a proxy for biodiversity, the diversity correlation should be made between lebensspuren and tracemakers, rather than with overall benthic fauna as no correlation has been observed in case of comparison with the latter.

Tracemaker and lebensspuren density: morphospecific relationship

Similar to previous research, tThe density comparisons between lebensspuren, degrading fauna and total fauna revealed no correlation, similar to previous research (Przeslawski et al., 2012). However, when the density comparisons comparing between lebensspuren and tracemakers revealed a positive and negative correlation can be observed (Fig. 4). The density of locomotion-feeding lebensspuren is inversely correlated with their tracemaker density while resting lebensspuren are positively correlated with their tracemakers densities. These group-specific correlations conflict with previous research that showed generally positive (e.g., Bell et al., 2013) or generally negative density correlations (e.g., Kitchell et al., 1978; Young et al., 1985). The difference with these previous studies may be due to the fact thatbecause their density comparisons considered the total fauna instead of separate functional groups (see Fig. 10 in Bell et al., 2013), not considering their specific impact on the sediment.

Trace residence time is the period during which a trace is recognizable on the sea floor before it is destroyed (Wheatcroft et al., 1989). ~~It is commonly accepted that~~ L~~l~~ebensspuren density values reflect the balance between lebensspuren formation and lebensspuren destruction/degradation either by biotic (e.g., microbial degradation, degrading fauna, epifaunal rate of movement) or abiotic factors (e.g., hydrodynamics, burial) (Wheatcroft et al., 1989). However, not all lebensspuren have the same residence time. T~~. T~~hus, traces not actively maintained by animals are ~~usually ephemeral features with lifespans~~short-lived, lasting only ~~of~~ days to weeks (e.g., faecal casts can be degraded within 1-2 weeks; Smith et al., 2005). In contrast, ~~while~~ locomotion-feeding and resting lebensspuren have ~~higher~~ longer residence times as they are impressions on the seafloor (see Fig. 8 in Wheatcroft et al., 1989 or Fig. 5 in Miguez-Salas et al., 2020). Very little is known about the residence time of dwelling lebensspuren, S~~s~~ome tracemakers ~~live inside~~inhabit them ~~for their whole life~~throughout their entire life, while others change ~~several~~ residence multiple times and their burrows get passively filled (Gage and Tyler, 1991). Thus, ~~-~~a wide range of residence times may be expected. However, ~~in any of the cases since~~irrespective of scenario, the sedimentation rate is usually low in the deep-sea and~~a,~~ dwelling lebensspuren should have higher residence time than wasting lebensspuren, and similar or higher than locomotion-feeding and resting lebensspuren.

~~In case of this study~~The ~~the~~ density of locomotion-feeding lebensspuren (e.g., ~~thick~~ M-ridged trails), ~~on the one hand,~~ was inversely correlated with tracemaker density. This ~~could b~~could be attributed ~~e~~to ~~for~~ two reasons: 1) a high residence time of these lebensspuren even if ~~while~~ the respective tracemakers may no longer be in the study area; and 2) these lebensspuren represent a foraging behaviour in which the tracemakers tend

Con formato: Sangría: Primera línea: 1,25 cm

to continuously search the seabed for food, often over a wide area (i.e., high rate of movement). Thus, a large quantity of lebensspuren may be produced by a single individual tracemaker in continuous movement. The density of resting lebensspuren (e.g., circular impressions, asteroid impressions)~~), on the other hand,~~ was ~~in this study~~ directly correlated with tracemaker density. This is not surprising because ~~even though~~while these lebensspuren have a high residence time, their tracemakers (e.g., asteroids, actiniarians) have low rates of movement (Durden et al., 2015; 2019). In such cases, a high density of resting lebensspuren should always be linked to a high density of their tracemakers.

The density correlation between wasting lebensspuren and their tracemakers showed a slightly positive but not significant correlation (Fig. 4). ~~Maybe this is due to the~~This may be attributable to the fact that ~~in some cases we were not able to~~we were unable to quantify the exact number of faecal casts for some morphotypes~~for some cases~~. For example, in station 4, the lebensspuren of the dominant tracemakers (*Elpidia*; more than 150 ~~specimens were~~specimens ~~identified~~) were in~~not~~ correctly quantified due to image resolution limitations (small rounded faecal casts). Thus, ~~presumably~~ a positive density correlation between wasting lebensspuren and their tracemakers should be expected. However, this assumption may be ~~disturbed~~ influenced by the behaviour of their tracemakers , as their ~~behaviours since their~~ feeding activity can be expected to depend on grain size, availability and quality of the nutrients among other environmental factors (e.g., Jumars and Wheatcroft 1989; Ginger et al., 2001).

The observed variability in the lebensspuren density correlations show a complex scenario even without considering biotic and abiotic factors that cannot be characterized through still images. For ~~example~~instance, it has been demonstrated that meiofauna and microfauna have the ability to smoothen and eventually fully erase surficial biogenic structures through small scale, grain-by-grain jostling of particles (e.g., Cullen, 1973).

These “small” biotic processes are impossible to quantify through images, however, ~~it has to be kept in mind that~~ these ~~will have affected also the~~likely influenced lebensspuren density that we quantified for this study. Moreover, while previous studies assumed that abiotic lebensspuren degradation rates are constant over the lebensspuren residence time period (Bell et al., 2013), ~~but~~ recent studies show that this may not be always true since hourly spontaneous events (e.g., benthic storms) may erase the full lebensspuren assemblage (Miguez-Salas et al., 2020). The effects of abiotic factors (e.g., bottom currents, substrate consistency) on the density of the studied assemblages as well as those of some biotic factors (e.g., microbial degradation which cannot be characterized in a still image) are out of the scope of this research but should be considered in future studies ~~and need to be kept in mind when interpreting seafloor images~~.

Conclusions

The neoichnological analysis of the KKT area reveals a general null diversity correlation between lebensspuren, tracemakers, and fauna while density correlations vary depending on the lebensspuren morphotypes. The further conclusions of this study are:

1. ~~The fact that the~~The ability of various tracemakers to produce the same lebensspuren morphotypes, and for a single tracemaker to produce various lebensspuren morphotypes, will impact the ~~can be produced by different tracemakers and one tracemakers can produce different lebensspuren will affect the~~ establishment of a positive or negative diversity correlation.
2. The existence of unknown tracemakers will contribute to the diversity correlation variability. However, lebensspuren diversity may be a good proxy

3. Lebensspuren density can be positively or negatively correlated with tracemaker densities depending on the specific lebensspuren residence time and tracemaker behaviour (e.g., locomotion, resting).
4. Lebensspuren-density correlations may be controlling on a wider spatial ~~global~~ scale by abiotic (e.g., hydrodynamics, grain size, organic matter, substrate consistency) and biotic factors (e.g., microbial degradation).

Above all, we suggest that lebensspuren density and diversity correlations should be done with tracemaker rather than with general benthic fauna.

Acknowledgments

Special thanks to the German Federal Ministry of Education and Research (BMBF) for funding this project (PTJ, Grant 03G0223A to A. Brandt). We ~~also~~ thank the crew of *R.V. Sonne* and ~~. We thank~~ M. Malyutina, the ~~Russian~~ coordinator of the Russian expedition ~~M. Malyutina~~. The research of O. Miguez-Salas was funded by a Humboldt Postdoctoral Fellowship from the Humboldt Foundation. This is contribution #18~~7~~ of the Senckenberg Ocean Species Alliance (SOSA). We extend our gratitude to ~~thanks~~Drs. Autun Purser and Rachel Przeslawski for their constructive comments, which significantly contributed to enhancing ~~who helped us to improve~~ the clarity of the manuscript. Special thanks to Anchita Casaubon for the English editing.

Table 2. Lebensspuren and associated tracemakers identified in the present study. Note that several lebensspuren can be produced by different tracemakers.

Behaviour	Morphology	Description	Tracemaker taxonomy	Notes
Dwelling	Mounds	Large, smooth-sided cone structures. The diameter of the mounds ranged between 5 to 20 cm.	Unknown~~Unknown~~	Probably crustaceans
	Single burrows	Single entry holes within the flat sediment surface. Occasionally, a smooth, cone-shaped mound with a burrow entry hole at the apex. The diameters were varied, as	Unknown~~Unknown~~	

		large as 2 cm, but usually between 0.5 to 1 cm.		
	Paired burrows	Two burrow entry holes that are closely spaced. The spacing between burrows was between 2 and 4 cm.	Bivalves and polychaetes~~Bivalves and polychaetes~~	
	Cluster burrows	Three or more burrow entry holes that are closely and randomly spaced. The spacing between burrows was between 2 and 10 cm.	Unknown~~Unknown~~	Probably crustaceans
	Lined burrows	Three or more burrow entry holes that are aligned following a rectilinear or slightly sinuous pattern.	Unknown~~Unknown~~	Probably crustaceans
	Crater cones	Large central mounds surrounded by distinctive clusters of round, shallow impressions.	Unknown~~Unknown~~	
	Crater	Depression holes related to the collapse of horizontal burrows	Actiniaria fam. indet. gen. indet. sp.3~~Actiniaria fam. gen. sp. 3~~	Probably also other actiniarians
Wasting	Rounded faecal cast	Neat, short spirals of thick faecal matter	Elpidia gen. inc. sp.1, *Scotoplanes* sp.1, *Scotoplanes* sp.2~~cf. *Elpidia.* sp. 1, *Scotoplanes* sp. 1, *Scotoplanes* sp. 2~~	Due to image resolution, *Elpidia* rounded faecal casts (which are commonly <1cm in size) have only been recognized on a few occasions (when it was in focus)
	Smooth faecal cast	Smooth thick faecal matter with a straight or slightly sinuous shape.	Pseudostichopus gen.inc., *Psychropotes* sp.1, *Psychropotes* sp.2, Synallactidae fam. inc. gen. indet. sp.1, *Benthodytes* sp.1~~cf. *Pseudostichopus* sp. *Psychropotes* morphospecies 1, *Psychropotes* morphospecies 2, *Synallactidae* morphospecies 1 (Amon et al. 2017), *Benthodytes* sp. 1~~	Smooth faecal cast from *Benthodytes* sp. 1 may present compressed appearance.~~Smooth faecal cast from *Benthodytes* sp. 1 may present compressed appearance.~~
	Mounded faecal cast	Discrete piles of faecal matter which are not associated with burrow entry holes.	Unknown~~Unknown~~	
	~~Coiled faecal cast~~ Coiled-curly faecal cast	Thick faecal strings appearing compressed and curled that may have ~~with~~ one straight coil at the end. May be present along thick trail lines.	*Psychropotes* sp.1; *Psychropotes* sp.2; *Benthodytes* sp.1 ~~*Psychropotes* morphospecies 1, *Psychropotes* morphospecies 2, *Benthodytes* sp. 1~~	Due to image resolution was difficu to differentiate between pure curl segmented faecal cast and oth similar morphotypes. Thus, all we included within this category.
	Knotted faecal cast	Tightly loop faecal trails, often with a characteristic loop-hook at the end.	*Peniagone* sp.1 to *Peniagone* sp.3~~*Peniagone* sp.1 to *Peniagone* sp. 3~~	~~The bigger morphotypes of this faecal cast belong to *Benthodytes* sp. 1~~ The bigger morphotypes of this faecal cast belong to *Benthodytes* sp. 1
	Wavy faecal cast	Tiny (less than 0.5 cm in thickness) meandering faecal remains with variable length and often in fragmented form.	*Peniagone* sp.1 to *Peniagone* sp.3~~*Peniagone* sp.1 to *Peniagone* sp. 3~~	Possibly formed by uncoiling of knotted faecal cast
	Switchbacks faecal cast	Switchback or meandering feature often beginning or ending in a spiral. The acorn worm is often observed making the feature.	Torquaratoridae gen. indet. sp.1~~*Torquaratoridae.* gen. sp. 1~~	
	Spirals faecal cast	Faecal spirals with both clockwise and anti-clockwise paths. The acorn is often observed making the feature.	Enteropneusta fam. indet. gen. indet. sp.1; Enteropneusta fam. indet. gen. indet. sp.2~~Enteropneusta gen. sp. 1, Enteropneusta gen. sp. 2~~	
Locomotion and Feeding	Rosette-shape	Small burrow entry hole with thick, radial spokes from the central burrow. Partially completed rosettes are commonly observed. Spokes vary in thickness and	Unknown~~Unknown~~	This trace is usually related with echiuran worms but none has been observed in this study

Con formato: Fuente: 8 pto

Con formato: Fuente: 8 pto

		length. Mounds are often found in close proximity to the rosette.		
	M-ridged trails ~~Thick M-trails~~	Complex concave crawling structures, ranging in width from 3 to 15 cm. Both sides of the trail have small sediment ridges (forming a M-ridged ~~shape~~ trail) due to the movement of the tracemaker through the seafloor. The trails are straight and most commonly sinuous; occasionally observed with the echinoids forming the track.	Asteroidea fam. indet. gen. indet. sp.1; Asteroidea fam. indet. gen. indet. sp.2; Echinocrepis sp.1; Echinoidea fam. indet. gen. indet. sp.5~~Asteroidea. fam. gen. sp. 1, Asteroidea. fam. gen. sp. 4, Echinocrepis. sp. 1; Echinoidea. fam. gen. sp. 5~~	
	Flat trails ~~Thick flat trails~~	Smooth concave trails of varying length with occasional small sediment puncture marks. Thickness ranges from 2 to 10 cm. Trails may form linear, meandering, or discontinuous paths.	*Benthodytes* sp.1, Psychropotidae, Asteroidea fam. indet. gen. indet. sp.3; Echinoidea fam. indet. gen. indet. sp.2; Echinoidea fam. indet. gen. indet. sp.7~~cf. *Benthodytes* sp. 1, *Psychropotidae*, Asteroidea. fam. gen. sp. 3; Echinoidea. fam. gen. sp. 2; Echinoidea. fam. gen. sp. 7~~	
	Variable t~~T~~hin trails	Smooth, concave trails of varying length, up to 2 cm thick. Trails may form linear, meandering or completely random paths	Gastropoda Gastropoda fam. indet. gen. indet. sp.1-6; Echinoidea fam. indet. gen. indet. sp.6~~Gastropoda. fam. gen. sp. 1 to Gastropoda. fam. gen. sp. 6; Echinoidea. fam. gen. sp. 6~~	Due to image resolution was difficult to describe any ornamentation within these trails. That is why they have all been grouped within this size category.
	Mounded trails	Smooth, with occasional ploughed features, convex trails of varying length and 3-10 cm thick. Trails may form linear, meandering or completely random paths. Craters appear sometimes in the middle of the trail.	Unknown~~Unknown~~	
Resting	Asteroid impressions	Asteroid star-shaped depressions with different dimensions. Diameter ranges from 1 to 15 cm.	Asteroidea fam. indet. gen. indet. spp 3, 4, 7, 8, 9 ~~Asteroidea. fam. gen. sp. 3, 4, 7, 8, 9~~	
	Ophiuroid impressions	Ophiuroid star-shaped depressions	Ophiuroidea fam. indet. gen. indet. spp 1-3~~Ophiuroidea. fam. gen. sp. 1 to Ophiuroidea. fam. gen. sp. 3~~	
	Circular impressions	Circular depressions with a depth of less than 4cm	Actiniaria fam. indet. gen. indet. sp.1, Actiniaria fam. indet. gen. indet. sp.3, Actiniaria fam. indet. gen. indet. Sp.7~~Actiniaria. fam. gen. sp. 1, Actiniaria. fam. gen. sp. 3, Actiniaria. fam. gen. sp. 7~~	

Table 3. Total number of lebensspuren, tracemakers, degrading fauna and fauna identified through the 8 deep-sea stations at the Kuril Kamchatka area.
